REPORT

OF THE

BUREAU OF INDUSTRIAL STATISTICS.

COMMUNICATION.

Department of Internal Affairs,
Harrisburg, Pa., July 28, 1899.

To His Excellency, William A. Stone, Governor of the Commonwealth of Pennsylvania:

Sir: In compliance with the requirements of the Constitution, I have the honor to submit herewith, for transmission to the General Assembly, the twenty-sixth annual report of the Bureau of Industrial Statistics, the same being Part III of the reports of this Department.

I am, very respectfully,
Your obedient servant,
JAMES W. LATTA,
Secretary of Internal Affairs.

181921

1—10—98

LETTER OF TRANSMITTAL.

Harrisburg, Pa., July 28, 1899.

Hon. James W. Latta, Secretary of Internal Affairs of the Commonwealth of Pennsylvania:

Sir: I have the honor to present herewith the twenty-sixth annual report of the Bureau of Industrial Statistics. The report covers the manufacture of silk, with illustrations, the entire production of pig iron, steel, iron and steel rolled into finished form, tin plate and limestone for iron manufacturing purposes, a continuation of the comparative series of 1892, and the comparative series of 1896.

Very respectfully,

JAMES M. CLARK,
Chief of Bureau.

INTRODUCTION.

The first matter that appears in this report is an article read by General Latta, Secretary of Internal Affairs, before the National Association of Officials of Bureaus of Labor Statistics of the United States, at its Fifteenth Annual Convention, held in Augusta, Maine, July 11-15, 1899, upon the subject, "Are Economics of Value in the Philippines?" While the Philippines are rather remote from Pennsylvania's field of operation, yet it can scarcely be said that they are too far removed to be reached by the broad science of economics. The subject has been made one of deep research, and the article will be read with profit by those interested in the science of government and in the advancement of the industrial conditions of the world.

The next subject presented is the silk industry, its culture and growth. It is carefully followed from the moth to the worm, from the worm to the cocoon, from the cocoon to the fibre, and from the fibre to the fabric, together with an outline history of its discovery as an article of value to manufacture, and showing how jealously the secret was at first guarded, and how it escaped from China; his wormship's march westward, and his final advent into America. The article closes with a presentation of the part Pennsylvania has taken in this field of manufacture, showing the almost phenomenal success she has attained. The illustrations, which are largely from our home plants, add greatly to the interest of the work, and will materially help in the better understanding of that which by reason of circumstances has been somewhat obscured in the past.

In the matter of statistics, the first tables presented are the comparative series of 1892 and 1896, where comparisons are made of the same establishments from year to year, showing, for the 1896 series, a comparison of capital invested, the value of the basic material out of which the product is made, the days in operation, the number of persons employed, the aggregate wages paid, the value of the product, and other deductions of interest; and for the 1892 series practically the same comparisons are made, except as to the capital invested and the value of basic material.

The comparative tables are followed by a complete census of the silk manufacture for the year 1898, showing the total number of spindles in use, both for winding and doubling, spinning and twisting,

and for braiding; total number of hand looms for plain broad goods, for jacquards and for narrow goods; the total number of power looms for plain broad goods, jacquards, ribbons and other narrow goods; the total number of machines for knitting and lace making, for sewing and for braiding; the total number of employes, both male and female, and of children, and the aggregate wages paid to each classification, as well as the total value of the production. Comparison is made between the Federal census of 1890 and the census of this Bureal for 1895, showing in detail the remarkable growth of this industry.

A complete census is also given of pig iron, of steel, of iron and steel rolled into finished form, of tin plate, and of limestone quarried for iron manufacturing purposes. The census of pig iron, iron and steel rolled into finished form, and tin plate, covers not only the entire tonnage, but values, persons employed, days of employment, and the aggregate wages paid, yearly earnings and average daily wage. Comparison is made between the years 1896 and 1897.

These figures have been compiled with great care, and may be relied upon as accurate.

ARE ECONOMICS OF VALUE IN THE PHILIPPINES?

By James W. Latta.

A saving, thrifty household is an economic household; a saving, thrifty nation is an economic nation. The widening scope of economy reaches beyond its domestic family environment, includes the state, and finds comprehensive expression through the qualifying word political. Between political economy and sociology there is close relationship, and with them both democracy has established a substantial intimacy. The mission of democracy is to break down caste, strengthen the family unit, enlarge the opportunity of the individual. Caste, primarily of oriental significance, has occidental application, where hereditary preferment is the distinctive social feature. It stands for the "dangerous aristocracy" that the unduly alarmed patriot feared that those equally earnest in patriotism but of alleged aristocratic tendencies and formidable in the wisdom of state craft had purposed to visit upon the Republic in the formative period of its existence.

Caste seriously impairs the basic principle of democracy, equality before the law. But democracy has more than fulfilled its purpose, its potent influences have not been confined to the geographical limits of its own domain. Our forbears aimed to secure for it no wider scope. Narrowed to a little fringe of free republics along the Atlantic seaboard, democracy was indeed a tentative undertaking. It was disassociated from every form of government, Asiatic and European, and out of fellowship with powers, potentates and rulers, insular and Continental. A hundred years have come and gone; the strength of the potentate has diminished; the power of the republic has increased. Experimental democracy is now substantial democracy, and the United States of America, where all color is alike, all creeds are equal, is the significant exponent of the people's sway.

Democracy is paramount in the western world, extends its touch to distant Africa, supplants an old Bourbon dynasty with the flag of the French Republic, and still maintains itself triumphantly in the mountain cantons of Switzerland. Parliament, diet, cortes, reichstag stand for the people in every court of Continental Europe; Islam and Slavic rule only are absolute, whilst every subject of the realm in all Her Majesty's vast dominions proudly proclaims himself a free-born Englishman. Equality before the law, if such in fact were not

its first conception, has enlarged itself to the equality of privilege, the equality of opportunity, the equality of ability.

Democracy accepts a new responsibility. It enters upon another tentative era. It proposes to assume the "white man's burden." Is it as fitted to regenerate the savage in distant lands, to direct an untutored civilization, to control colonial possessions as it is to be mandatory in an "indestructible union of indestructible states?" The right of territorial acquisition of contiguous boundaries was determined by the Louisiana purchase. The stricken political conscience of the strict constructionist yielded its constitutional convictions to an opportunity too advantageous to be neglected. Sovereignty is a sweeping concession. The right to declare war, to wage war, must confer the corresponding right to accept the responsibilities, adjust the differences, to solve the conclusions involved in the consequences of war.

Will economics he helpful, sociology of value, statistics of advantage to this enlarged purpose of democracy? Are their principles applicable, their aims available for the conditions prevalent in our new possessions? In the Philippines, statistical information seems to have been limited to the market quotations, the custom house manifest and the readings of the thermometer in the city of Manila—meagre details for helpful economic aid. The economic arts have no abiding place until the social compact has broadened to a national existence. The economist has no tools in his workshop to fashion betterments for a primitive people unwilling to abandon the tribal relation and accept the state as the institution of right. Nor even then are his implements adjustable for a people who fail in the possession of a national conscience. The knowledge of the right and the wrong of it, acquired through a pagan civilization, is a sterile domain for the propagation of a thrifty economic harvest. The failure of the Englishman to realize the full fruits of his labor in his oriental undertakings is because of the unregenerate millions who people his vast East Indian possessions. Almost fifty years ago John Bright said of India, "Educate the people, govern them wisely, and gradually the distinctions of caste will disappear." Neither wisdom of administration nor offers of a beneficient training have fulfilled the assurance. Wedded to caste, true to the traditions of an idolatrous priesthood, the East Indiaman declines advice to be frugal in years of plenty. Famine is his direst foe, yet he refuses to be provident in methods and measures to alleviate the miseries or avert the depopulation that follow its stalking ghost so often abroad in a land so abundant in sunshine that if wanton drought did not at times assail it, it would be ever the richest of man's belongings. "Enlightened government and modern civilization: these are the specifics for famine. Where they exist scarcity will never result

in depopulation. Where they do not, the utmost endeavors of government may mitigate, but they cannot avert." (Hunter's Annals of Rural Bengal, p. 55). Great epidemics originate beyond the borders of christendom; within its limits famine is rare and pestilence infrequent. Caste is the formidable hindrance to the complete reclamation of a Hindu civilization to the white man's standard. Willing to accept a western sovereignty, unwilling to yield to its proffered education, the enfeebled Hindu mind clings vigorously to an hereditary philosophy that blights personality, impedes progress, destroys usefulness. The Hindu has no fear of disturbance in his religion. Save that he has been halted in his cruel sacrifices, his faith is guaranteed him. The Empress of all the Indies has assured him by official proclamation that the state shall in no way interfere with his creed.

This tenacity of religious purpose in these worshipers of strange gods is not limited to the boundaries of the East Indian peninsula. A pagan civilization grown up about an idolatrous devotion is resentful of interference. The savage seems more willing to surrender his fetish than does the pagan his philosophy. Stunted moralities, the survival of fetish beliefs and pagan practices, are barriers that will clog the humanities in an early redemption of the Philippines. In scientific research and intelligent travel no American has better acquaintance with that archipelago than Prof. Dean C. Worcester, of the Michigan University. In his recently published work, he says: "The total population of the archipelago is not definitely known, as census returns are necessarily inaccurate, but it is usually estimated at from eight to ten millions. It is divided between more than eighty distinct tribes, which, for purposes of discussion, may be conveniently grouped as Negritos, Mohammedan Malays, pagan Malays and civilized Malays." And this is his judgment of one of these numerous tribal subdivisions; "I have elsewhere given in some detail my estimate of the Mohammedan Malays or Moros. I consider it certain that the nation which would have any hope of getting on peaceably with them must let their religion strictly alone; certain too, that for many years to come they must be held in check with a strong hand."

Mr. John Foreman, of the Royal Geographical Society, in his instructive work on the Philippines, a London publication of 1890, thus measures the domesticated natives of Luzon, the Filipinos: "Amongst themselves they are tyrannical. They have no real sentiment, honor or magnanimity, and apart from their hospitality, in which they far excel the European in all their actions, they appear to be only guided by fear or interest, or both. * * * "No one who has lived in the colony for years would sketch the real moral portrait of virtues and vices." * * * "Nor do the na-

tives, rich or poor, of any class in life, and with very few exceptions in the whole population, appear to regard lying as a sin, but rather as a legitimate though cunning convenience, which should be resorted to whenever it will serve a purpose. It is my frank opinion that they do not, in their consciences, hold lying to be a fault in any degree."

Prof. Worcester confirms this estimate in language equally convincing. "The civilized natives," he says, "seldom voluntarily confess faults, and often lie most unconscionably to conceal some most trivial shortcoming. In fact, they frequently lie without any excuse whatever, unless it be the aesthetic satisfactiou derived from the exercise of their remarkable talent in this direction. When one of them is detected in a falsehood, he is simply chagrined that his performance was not more creditably carried out. He feels no sense of moral guilt, and cannot understand being punished for what is not, to his mind, an offense."

A recent magazine article quotes, from an undisclosed authority as follows: "A studeut who spent fifty years here (Manila) is quoted as saying, 'the native is an incomprehensible pheuomeuon, the mainspring of whose thought and guiding motive of whose action has never yet been, may never be, discovered.'" While General Otis, in respouse to an interviewer who inquired whether his idea concerning the native character had changed since the recent outbreak, replied, "No one understands the native character."

These estimates of native moralities would indicate that the Filipiuo "is lost to that veracity of mind so essential, as Carlisle has pointed out to the successful existence of men and nations." A basis so deficient in the social virtues offers but a flimsy superstructure upon which to construct a conscience trustworthy for the maintenance of internatioual obligations consequent upon indepeudeut statehood; presents an insecure foundation for economic development and industrial growth.

Goldwin Smith resolves the elements of human progress, and thus, as he phrases it, of universal history into only three, "the moral, the intellectual, the productive." And Herbert Spencer, associating the same thought with the effect of population upon those portions of the earth's surface capable of sustaining it, says "After having caused, as it (population) ultimately must, the due peopling of the globe and the raising of all its habitable parts into the highest state of culture; after haviug brought all processes for the satisfaction of human wants to perfection; after having at the same time developed the iutellect into complete competency for its work and the feeling into complete fitness for social life—the pressure of population must gradually bring itself to an end."

Is the Philippine archipelago one of the habitable parts of the globe

likely to be raised to the highest state of culture? It answers responsively to the pressure of population. The area of the Island of Luzon alone more than equals in extent the State of Pennsylvania, while its estimated population is not far short of the number of inhabitants in that favored commonwealth. Are the racial conditions an insuperable barrier to intellectual development, moral progress, a complete fitness for modern social life? There is probably no territory of equal extent where savagery, barbarism and civilization are severally in such significant evidence. As John Fiske designates it, "Barbarism is the enormous interval which begins with the invention of pottery and ends with the invention of the alphabet." Civilization consequently beginning with the invention of the alphabet, according to the French philosophers, exists in various degrees and is susceptible of continual progress. The savage, "is an uncivilized human being, one in the lowest and most primitive state of society." Luzon savagery is not of the worst, its barbarity not the most offensive, nor is its civilization of the purest. The combination would embarrass the idealist, the situation stagger the reformer. To treat the question superficially, there could be but the one conclusion, to sacrifice philosophy, forego morals and let the Filipino take care of his own deliverance. There is, however, one of Goldwin Smith's three sub-divisions so available in these islands for the application of economic principles, that with its better development the higher development of the other two might follow as a fitting sequence. There is no soil of more productive affluence within the zone of the tropics than that of this archipelago. The people have shown a capability of applying the industrial arts to the fabrication of much of this affluent product, with intelligent guidance this fabrication might be utilized to high commercial advantage.

There are physical hindrances. Never to worry and not to work are co-incidents of tropical temperament. All nations begin by being agricultural, but with a soil so prolific as to yield, without assistance, a sufficient sustenance there is no incentive to labor. The morrow takes care of itself. Neither is there invitation to an Anglo-Saxon emigration. The benefits the native may derive from an acquaintance with Anglo-Saxon enterprise can come only from the touch he is permitted to enjoy with Anglo-Saxon methods. No white man can discharge his daily toil under the withering influence of a tropical sun, except he be of a Latin race. There is no need longer, either to find a home for conscience sake. A universal tolerance has stayed the flight from persecution. The intellectual and the moral in proper ethical order precede the industrial development. The Pilgrim and the Puritan, Cavalier, Scotch-Irishman, Quaker and Huguenot recognized the precedence and each landed upon the shores of his new American home with the Bible and concordance in one

hand, the arithmetic and spelling-book in the other. As they tore the rocks asunder in New Englaud, leveled the primitive forests in the Appalachian basin, found a more bountiful yield in the Savannahs of the south-land, they overcame all natural resistance and found advantage and opportunity in their every undertaking. But they never forgot the ethical precedents. Their beliefs and their scholarships kept pace with their opportunities. They met their dangers with their fortitude, surmounted their difficulties with their energies, and while learued theologians gave them better understaudiug of their creed and encouraged wider dissemination of their faith, they found iu their Belles Lettres rhetoric and mathematics a higher intellectuality than was supplied them in their primer and arithmetic.

Why may not climatic and social conditions justify a reversal of the sequence and an intelligent morality be coustructed from a proper industrial foundation? Why may not a neglected and abandoned people, inhabitants of a land of wondrous abundance, have their productiou so intelligently directed that they may be ultimately willing to accept the ethics of christendom, attain a public conscience, be trained to the responsibilities of state craft? The native's prefereuce would probably be to be goverued well aud let strictly alone as long as he obeys the law. It is said he has no patriotism in the sense of the white mau's uuderstanding. But the North American Indian had no patriotism except as crude savagery was an incentive to its development, yet he held tenaciously to his exclusive right to the occupancy of the couutry over which he roamed, and fought viciously against iutrusion on or seizure of his vast nomadic belongings. Yielding to the inevitable, afters years of bitter conflict, where he still iusists on maintaining his tribal relations, he at least contents himself on his reservation, or, williug to abandon those relations, finds still better satisfaction in his fee simple title to the holdings the Government has allotted him. He was slow to accept this, the first step of civilization towards personal betterment. So, too, may it be with the Talagol peasant. His Spanish master never taught him the advautage of proprietorship. He was sometimes permitted, when one piece of property was iuconvenient of tillage, to wander to another, better suited to serve his purpose. If the responsibility of his American protectorate shall be to locate him on his belongings, assure him against intrusion, secure him against ouster, he may learn to know that land ownership strengthens the family unit as the stable beginniug of the social compact.

Nor did the Spaniards wholly fail to recognize proprietorship as a civilizing initiative. They made at least one attempt at land allotment. A better selection for the test could have been secured from among the domesticated natives. Instead, however, a wild tribe

of mountain nomads was chosen for the experiment. Holdings were set apart, stock supplied and implements furnished, but within a year the lands were all abandoned and the tribe was back again to its home in the mountains. The fact that the best available lands are held largely by the monastic element, either through undisturbed possession or government grant, with the domesticated natives as tenants, may have restricted the test to a location and people least likely to support it.

An eminent writer on economics, Prof. Arthur Latham Perry, substituting value for wealth as a word of higher technical significance, says, "The three only valuables are, in short, material commodities, personal services and commercial credits." The Luzon native, as with the vast majority of the species everywhere, regardless of race or surroundings, makes his contribution to productivity, entirely almost, through the one direction, personal services. If his wants are confined to the little apparel a tropical environment demands, and his desires are limited to the little food these softer climes require, his contributions will be proportionably lessened. Some incentive to increase his wants and multiply his desires would follow, if beyond his needs for personal consumption the product of his service could be safely called his own. If his labor could be associated with land to which he might justly claim proprietorship, he would be made to understand that his surplus commodities were the subject of barter and exchange for other commodities essential to his other wants and his other desires, that his touch with his neighbors, themselves proprietors, would necessarily create. He would soon learn to know that a body politic so constructed, allied to the commercial centers, would possess advantages and opportunities with which before he had no acquaintance.

Under his Spanish dominancy the domesticated native has been seriously restrained. Besides a burdensome taxation, under the vicious system permitted by the authorities, a landlord owned everything but the native himself. Himself he could remove, but not so his belongings. The betterments and accumulations followed the land and the tenant's interest in them ceased when he changed his locality. His lease, too, was frequently so cunningly drafted, the metes and bounds of his holdings so indefinitely set out, that another occupant more favored by the proprietor had sometimes forcibly ejected him before his tenure had run its course.

All nations, as has been said, begin with agriculture. So far as its immature developments have advantaged its units, the social compact in the Philippines is scarce beyond its beginning. Through all the centuries of this improvident beginning, the masses of the natives have so far subsisted solely by the contribution of personal services. As a fact, the native knows no more of economics as an

art than did England after the plague in London. Labor, woefully diminished in supply, met the demand for its employment by fixing rates commensurate with the diminution. The Parliament as yet unacquainted with the inexorable law of supply and demand, sought to limit the wage to the prices prevailing before the depletion. The attempt was a failure, the law of the realm yielded to the law of economics and the wage earners' bargain was made upon the conditions of the market.

Practically, therefore, at the beginning of his national existence, at least of such a national existence from which he may fairly anticipate substantial benefit, if beside his personal services the valuable, which no man is really without, the native could be permitted the acquisition of landed interest, he would speedly begin acquaintanceship with another of the valuables, material commodities. And though his touch with the commercial credits may be yet afar, if encouragement be given to this, his first introduction to the material commodity, he is making closer acquaintance with commerce and its credits than he ever had opportunity to do under the old regime. While the commodity is an essential to the commercial credit, the personal service is but the incident of the one and the adjunct of the other. The intimacy of the two former is closer than that of the latter with either of the other two. It is of remote origin, and land of all the material commodities is first recorded as a subject for exchange. Two thousand years before the Christian era dawned, Abraham, as an eminent economic writer cites it from the Scriptures, bought the field and cave of Machpelah for four hundred sheckles of silver current money with the merchant.

Biblical authority is silent as to the nature of the title Abraham acquired, whether the grant was in fee or an easement of sepulchre only. The possession assured to him with such public formality "in the audience of the sons of Heth," would indicate that his title was indefeasible. He dedicated his purchase, however, to purposes of burial only, a gruesome beginning in far off Hebron of the world's real estate movement.

Sentiment has no place in the hard science of buying and selling. It takes two to make a bargain. The meeting of the two minds consummates the contract, each to do what he has agreed to do without diminution, without evasion. Common honesty is alone the ethical basis of the transaction. There is some sentiment though that follows the soil. It is one of God's free gifts to man—not to foster indolence or propitiate sloth, for with the gift has gone forth the edict "by the sweat of thy brow shalt thou earn thy bread." Public policy is no stranger to the purpose that seeks through a unity of title in labor and in land a surer national stability. The new and the old world have both been liberal in their invitation to individual occupancy,

the one to encourage emigration, the other to restrain it. The homestead laws of our own country opened our vast western domain to the thrifty and adventurous pioneer, while now Holland seeks to check the appreciable depletion of her population by the reclamation of that portion of the soil covered by the Zuyder Zee most profitable for agriculture, and dispose of it to individual purchasers only. It is a gigantic undertaking, attended with enormous cost. That the scheme may be the more effective as an anti-emigration measure, the acquisition of title by trusts and corporations is specifically forbidden, and the prices per acre are made attractively low. Indeed, if the government is likely to pursue the same liberal policy with its colonial possessions as it has with its territories and encourage Filipino settlement with a land allotment, the white man may seek to be an active competitor in the distribution. An officer on duty in the Philippines watchful of opportunities, in homely but cogent phrase, not only sustains the economics of the proposition but observantly forecasts the outcome of the situation. In a letter that found its way to the public prints, he says, "I take no stock in the cry that white men cannot work in the tropics. They can, when working for themselves."

Two recent writers, in contributions to current magazine literature, with a philosophy that deserves a better preservation, seek, through the subjects upon which they respectively treat, to impress upon their readers the conclusion that the "altogether good" is unattainable both by men and by nations.

Of mankind, says one, "The human heart is a strange compound of good and evil, the proportions are unknown even to ourselves, but one thing we may know with certainty, no human being is altogether good or altogether bad."

And of nations says the other, "It happens that 'in the corrupted currents of this world' it is impossible for men or for nations in all their conduct to be governed by strict abstract right."

The estimates of the native character have heretofore been valueless. As has been said, the attempt at estimation is a fruitless undertaking. The application of this philosophy to the negative conclusion drawn on the native's better side, would probably grade him in that class of human beings not altogether bad. His glaring fault is that he will lie. He is vacillating, uncertain, unreliable. He cannot be depended upon to follow a fixed vocation. While fitting himself for an intellectual pursuit, he is as likely to abandon his purpose for menial service as he is to continue his training. "Situations create duties." No situation has ever been created for him where it was clearly demonstrated that he owed either to himself or society a duty to maintain it. If he shall sow and reap and exchange and barter with the personal independence incident to proprietorship

there is at once a creation of duties to himself and his fellow man clearly manifest in the very situation itself. There are "cheery notes," though, in all this "chorus of disparagement." The Filipino is apt with the loom and the spindle, there is a sunny side to his nature, he delights in music. Filth and intemperance are the besetting evils of the undeveloped races. The hurtful ills of intemperance have been a pernicious barrier to civilizing influences. The depravity that follows it is still, in many localities, a potent hindrance to a better advancement. The Filipino is free, entirely free, from both these evils. He is sober and cleanly. Free from the irritation and despondency of intoxication, he is patient and forbearing. In his cleanliness of person he is a model, in the neatness of his household a pattern. Civilization belongs by origin and nature to the sterner climes. It is there found in its better maturity. In the tropics, with the native races at least, it is "an exotic." It must be nurtured tenderly, developed prudently.

The Dutchman has been thrifty as an emigrant, successful as a colonizer. His aim was economics. His only politics were the politics that assured his acquisitions. If the betterments of civilization came of his occupancy they followed as an incident, not as the intent of his mission. As an immigrant, he fled from Spanish persecution, settled in southeastern England, and, teaching the English artisan new lessons in craftsmanship, impelled the British nation to the higher attainment of its vast industrial development. As a colonizer, he took Java, with her fifty-two thousand square miles of undeveloped soil and her five million semi-barbarous people, and with his so-called "culture system," in less than half a century, increased the population seventy-three per cent., and made the island a garden spot of vast "exqusite beauty," "the finest and most interesting" in all the tropic zones. He opened schools in the most populous districts, but forbade his priests and clergy to proselyte the native. His "culture system" was realistic nationalism long before the exposition of the new philosophy. The native tills the soil, the government takes the product and profits are shared between them.

The recent experiences of a traveler of reputation in far off eastern Asia are illustrative of the fact that with all our nineteenth century progress we are still abreast with the rural simplicity of pentateuchal times. In the lengthy journey from Pekin to St. Petersburg he thus cleverly describes the change as he crosses the Mongolian-Siberian frontier: "Although their land was richer, the people seemed less well-to-do. Their tents were smaller and poorer. They seemed to be more eager for money, more on the outlook for 'tips,' less ceremoniously polite. In a word, we had passed from a nomadic and pastoral people, content with their flocks and indifferent to money, and were among a people so much in touch with civilization that

they knew they were poor." They were disturbed by the debasement of penury, but not yet awakened to the refinement that rejects the proffer of the unwilling gratuity. Their perceptions were quickened by a new presence that supplied the satisfaction of desires with which in their more primitive state they were wholly unacquainted. Their rude speech and coarse life had not prepared them for the self-dependence of personal energy. They had not yet learned that mendicancy is repulsive to manliness, that poverty has its dignity as well as riches. An equally crude acceptance of christianity pervades the heathen border line. A first acquaintance with the forms of worship is not always accompanied with a proper spirituality, and when it is sought to exhibit proficiency, the missionaries tell us that it is sometimes with difficulty that they suppress the convert's demand for tobacco before, as the convert styles it, he will furnish his hallelujah. The Philippine islanders are largely a nomadic people. They may not now know that they are poor. They will when they touch American civilization and begin to know American ways. Where there are landed estates they are large and their titles are not wholly secure. Most of that land seems to be practically vacant and awaits pre-emption.

Money, a thing of value, a medium of exchange, is as well a solvent. Its introduction supplied the first method for distribution. Until a standard was devised for the determination of value, wealth was incapable of measurement. The flocks and herds and lands and possessions stood for themselves alone. They were substances of intrinsic worth, but with no calculable value. Their possessor was at the same time a rich man and a man of station; with his wealth was his influence; with his station his authority. There were no middle classes; it was riches for the few, poverty for the many. The poor were held to service, dominated by the authority, awed by the possessions of the rich. There was no way to distribute the lordly holdings of the master until something of representative value was invented into which these holdings might be ultimately converted. The poor man could have no hope or expectancy of like enjoyments with the rich, the estates were too vast, the leap was too great, there were no steps of gradual approach. What was to be the medium, the intervention of which would permit their acquisition in lesser proportions, where the possessor of the medium did not control it in sufficient volume to secure the whole? Abraham applied the first practical test when he converted a surplus from his vast Egyptian proprietorship into money and then invested that money in a real estate operation in distant Hebron.

It was "one of the initial steps in the progress of civilization," when "money current with the merchant" was devised as the expedient to relieve the difficulties and remove the hindrances incident

to the direct exchange of services or materials, each for each, or the one for the other. Its earliest functions were to break bulk, to expand trade, to save time, to eliminate distance, to equalize commodity balances. It encouraged association, engendered confidence, relieved the feebleness of isolation, awakened a sense of personal dignity, strengthened individuality.

The fulfillment of all these intendments in our new possessions, though distant, is yet attainable. Only the domesticated natives know of money and its purpose. Mexican silver, the currency of the commercial centers, does not invite confidence. Its value fluctuates. Too bulky for convenient carriage, it has encouraged a pernicious system of small credits, that frequently involve serious losses. Counterfeit coin is plentiful. Good money, the mutual confidences of commerce, the independence of land proprietorship, are sterling factors upon which the economic evolution of the Philippines must eventually be dependent.

Christianity, the hand-maiden of civilization, is confined to the few, and filtered, as it has been, through a debased priesthood before it has reached its converts, it will afford but little succor towards the leaven of the unregenerate masses. Policy, propriety, safety forbid interference with pagan practices, heathen beliefs, the worship of false goods. The Commissioners have guaranteed immunity. Intelligence, integrity, capacity have been hindered rather than encouraged through the centuries of touch the Filipino has maintained with his Latin ruler. Only a long and acceptable acquaintance with the Anglo-Saxon and his methods can accomplish for the natives of the Philippine archipelago what they are manifestly unfitted to accomplish for themselves.

In a recent communication to the Navy Department, Admiral Dewey concisely and intelligently epitomizes the situation.

"Although," says the Admiral, as he concludes his report, "under the rule of the United States, the character of the natives will certainly improve, a sudden change is not to be expected. A few of them might be employed on transports and vessels of that kind; indeed, the Filipino quartermasters who have been serving on the Nanshan and Zafiro since the purchase of those vessels, have always been satisfactory, but because of their long association with Americans and Englishmen they belong to a class apart from the great majority."

The unconscious tribute of the Admiral to the fruitfulness of Anglo-Saxon association inspires a hopefulness that that association will solve the problem of Philippine regeneration. The efficacious results of the long familiarity of the small minority with an American and English opportunity must be equally beneficial when a like propitious advantage is afforded the great majority. The successful ministration of the economic sciences only awaits closer intimacy and wider dissemination.

THE SILK INDUSTRY.

For information contained in the following article on Silk Culture, the Bureau is largely indebted to the American Silk Journal Co.

GENESIS AND INITIAL PROCESSES.

The silk manufacture having attained a commanding position in this Commonwealth, its growth within the past few years being altogether phenomenal, unequalled by anything recorded of the industry in the annals of any other state since the manufacture was established in this country some sixty years ago, it seems eminently proper that somewhat as to the origin and processes and also an outline history of the "Queen industry," also somewhat as to processes of manufacture be presented in this work. It is proposed merely to sketch those earlier stages of silk culture and manipulation and pass rapidly on to the pleasant task of chronicling the first beginnings and subsequent advancement of the fascinating industry in our State, where, since it was planted and became firmly rooted in the soil, it has grown to goodly proportions, adding largely to our material prosperity and affording food and shelter to thousands of thrifty and industrious workers in nearly fifty towns and hamlets throughout the Commonwealth.

Imprimis, a few words as to the character of the silken fibre. It is a curious fact that for silk, of all filamentary substances, that which gives the finest, most durable and most elastic thread, with a tenacity equal to that of good iron (that is to say, a thread of silk of like size to one of iron will support nearly the same weight before breaking); a filament, too, that lends itself to the production of the richest, most costly and most beautiful of all known fabrics, we should be indebted to a repulsive worm; but it is even so.

Silk is a liquid, gummy substance, secreted by certain insects from their food, and is contained in cells or tubes on each side of their bodies, and at their volition is drawn out through the minute orifices of the organs called "spinnerets." From two to six of these filaments, being united as they are drawn out, harden and strengthen and form a fine but remarkably strong thread, which is used by the producers themselves for a variety of purposes. Some, like the silk-spinning spider family, use the threads in forming a kind of suspension bridge on which to travel back and forth; also in forming traps, or webs, wherein to catch their prey.

But our interest centers chiefly in the caterpillar silk spinners, which form a cocoon of their thread and, entombing themselves therein, pass into a chrysalis state. We may still further narrow the

Figure No. 1. Silk Worm.

subject to the Bombycidæ family, which do not attempt to spin until they are ready to pass into that state, and even of this family there are but twelve to fifteen species whose cocoons are available

FIG. 3. Transferring Moth Eggs from the Mulberry Leaves. (See page 21.)

for commercial purposes. Best of all is the genus Bombyx, which feed by preference on the leaves of the white mulberry (Morus alba), though they may be reared in other foliage, including the Chinese mulberry (Morus Multicaulis), the osage orange and a few others. (See figure No. 1.)

The Chinese and Japanese who pet their silk worms almost as they do their children, have some odd names for the different species of good spinners, among them being, according to the Chinese work, Tsan-hing-shu, "The Silk Worm with the White Head," the "He-tsan," or "black silk worm;" "Hoi-cul-tsan," or "ash-colored child;" "Kin cul-tsan," or "gold-stuff child." The cocoons of the Japanese silk worms are mostly of a pale green color; those of China, white or yellow, sometimes tinged with green; those of the best districts of Turkey, pure white; those of Italy, yellow.

We will now take the silk worm at the stage of its changeable existence, when it is in the form of a moth miller or perfect insect. (See figure No. 2.) In this form it enjoys but a brief life, from two or three days to a week, during which the female lays about 400 to 500 eggs, about the size of a mustard seed. These usually adhere by a gummy substance to the mulberry leaves, whence they are carefully removed, usually with a feather, to sheets of paper. (See figure No. 3.) The eggs may be kept in a cool place without hatching for months; they are an article of commerce and may be and frequently are carried around the world.

When the foliage food is ready for the young worms the eggs are placed in the proper temperature and are hatched, the worms being at first about one-twelfth of an inch in length. Immediately they develop an insatiable appetite and devour twice their weight daily of mulberry leaves as they are fed. (See Figure 4.) Under varying conditions they attain their full size in from twenty to fifty-six days, during which they cast their skins four times, while in a lethargic state. Fully grown, they are about three inches in length and have increased in weight from 1-100 of a grain to 80 or 90 grains, or 8,000 times their original weight.

Now the worm will spin. Attaching himself to a twig, he builds the outside of his cocoon first, then, turning himself over and over towards the center, paying out his silken cable as he goes, he continues the work until he has spun himself nearly to death, and he has walled himself into a cocoon, formed of a delicate gum-matted thread five hundred to a thousand yards long, the only example on record of a living creature retiring into a hole and "pulling the hole in after him."

Just here his life ends by transition to the pupa or chrysalis, which, in from twenty to forty days, is ready to eat its way out, transformed again into a joyous moth or butterfly, who would at once seek a mate

and repeat the reproductive process above described, but man steps in and kills the moth by placing the cocoon in steam or a hot oven, as his exit would break and destroy the cocoon fibres or thread, leaving what is known as a pierced or perforated cocoon, of value only as waste, of which we shall treat later on. Thus, paraphrasing a time-worn adage, the worm proposes but man disposes, and rings down the curtain on the "continuous performance" ere the commercial value of the cocoon is impaired. (See Figure 5, showing cocoon, with worm inside, and Figure 6, showing pupa or chrysalis lying in a state of torpor within.)

Figure No. 2. Moth Miller.

And now that we have achieved a perfect cocoon we have to reel the delicate fibre, a most important work, as the value of the raw silk depends largely upon the manner in which it is performed. There are two methods; it may be reeled by hand in households of the growers, by the crudest and most primitive appliances; or it may be done at a government filature, where the reels are operated by power and the work is performed with the utmost skill and by experts, with improved methods. The Chinese product is mostly "country silk," which must be re-reeled before it is fit for use. America gets the very best raw material exported from all silk-producing countries, it being found most economical; owing to the higher wages

FIG. 4. Feeding the Worms. (See page 21.)

paid for labor, it does not pay to use inferior sorts. In Japan, the reeling is largely done at the filatures.

The implements used to convert the cocoons into silk are most simple in all countries in the world. (See Figure 7.) They consist principally of a basin and a reel, the basin containing warm water to loosen the gum from the outside layers until the ends of the threads can be caught up. A union of these threads from several cocoons forms the raw silk of commerce. The reeler dextrously unites them in their soft state, and they are given a peculiar twist and a pressure that causes them to adhere as one filament. The number thus united depends upon the standard of raw silk sought to be produced. The silk has yet to be put into hanks for baling in readiness for shipment, and this process is shown in Figure 8.

In all these processes in the preparation of the silk for export the cheapest labor of the orient and of Italy is employed. Girls in Japan are paid from five to seven cents a day and board, which latter is counted at three or four cents a day. Female weavers receive as high as ten cents a day; male weavers, fifteen to twenty cents and board themselves. The "board" consists of a little dried fish, thin gruel, barley tea and sometimes a few vegetables. Working hours are from 5 A. M. to 10 and 11 P. M. seven days in the week. In China wages are, if anything, lower; in Italy they are from one-third to one-half more than in Japan.

A few words just here about the article known as "spun silk." Allusion has been made to the pierced or perforated cocoons from which the moths have emerged and which are spoiled for reeling through the cutting of the fibre. These, together with all inferior, unreelable cocoons, filature waste, mill waste (the tangled and broken threads resulting from the handling of the fibre during the many processes it must undergo), and even the sweepings from the floors, form the basis of spun silk products. The difference between waste and ordinary raw silk is simply a lack of continuity of fibre. The former must be combed straight, ungummed, passing through many processes, then carded and spun much the same as flax or cotton.

The machinery employed in this branch is built almost exclusively in England and is exceedingly delicate, peculiar and costly. Ordinary waste has a most unpromising appearance, as being practically valueless, but when fully prepared for spinning it looks like the whitest of combed fleeces, and gleams with the lustre of spun glass. Any standard of thread or yarn required can be produced from it, and very superior fabrics also are made, wholly or in part, from this material. It is largely used in conjunction with reeled silk, the best effects being produced by using the more brilliant reeled silk for the surface of the fabric and the spun silk for the body; to achieve a dead surface with lustrous figure this method is reversed.

Of late years the most marvelous and effective machinery has been introduced in France and in England for the disintegration and utilization of silk chiffon, or rags, which are put in the machine at one end and emerge from the other end in carefully classified filaments of uniform length and fineness, ready for spinning. None of this work is done in this country, and the establishments in the United States, where ordinary waste is manipulated, are few in

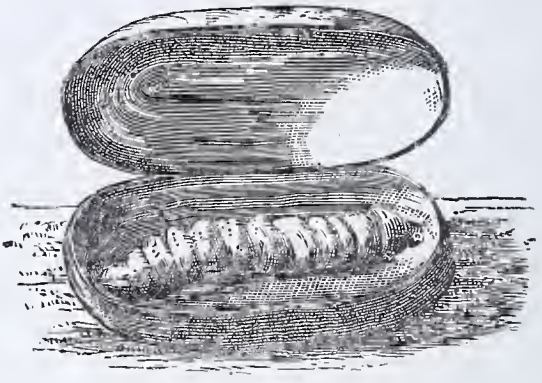

Figure No. 5. Cocoon with Worm Inside. (See Page 22.)

number—not more than half a dozen in all—the spun silk industry not being especially strong with us, though the product fills a certain place of its own in the market and supplies a cheap and serviceable material.

Only a small space of the limited amount that can be afforded to a sketch of the silk industry may be devoted to a glance at the several

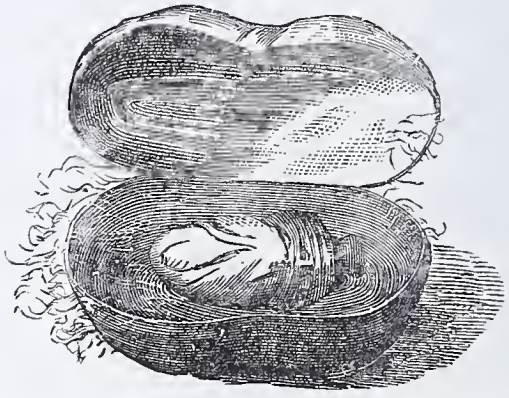

Figure No. 6. Chrysalis Lying in a State of Torpor. (See Page 22.)

substitutes for the product of the silk worm; and first and most interesting among these is the product of the silk-producing spider, comparatively small in quantity, owing to the uncertain tempers of this class of spinner, but of exquisite quality and almost priceless value. Queen Cleopatra's robe, that could be drawn through a finger ring, is thought to have been made of spider silk.

The great difficulty is to procure a sufficient number of spiders,

FIG. 7. Converting Cocoons into Silk. (See page 23.)

since they cannot be—or have not yet been—bred and reared like silk worms, so as to maintain a continuous industry.

Another difficulty is found in inducing them to relinquish their web; some, especially the large Madagascar spider, which is a prolific spinner, are exceedingly ugly and vicious.

Quite recently, the London Society of Arts offered a premium of £1,000 for a practical method of producing spider silk, and an entomological Frenchman, M. Cachot, has claimed the award. He has, at his place near Paris, a vast number of spiders, of all species, and has succeeded in reducing them to a fair state of control, so that the quantity of silk drawn from them is quite considerable. He has constructed an ingenious device in the form of an automatic slowly-moving reel (See Figure 9, to which the web it attached, the pull being just sufficient to induce the spider to resist the tension and make him a confederate in the robbery of his own product; he thinks he is spinning his web.

When one spider is "spun out," he is detached and put away, to be fed and petted, and another is substituted until the bobbin is filled, and so on. It will be seen by the foregoing that this ingenious Gaul has discovered a much better way than that of the tidy housewife, whose only idea of the proper treatment of spiders is to chase them into a corner of the ceiling and crush their lives out with a broom.

A number of so-called substitutes for "silk worm silk" have been exploited of late years, the first to appear being that of Count Chardonnet, of France; the second, that of Dr. Lehner, of Augsburg, Germany, now operating in Switzerland. Both systems are based on the idea of producing imitation silk from the same material as the silk worm feeds upon, thus eliminating the ancient and original spinner altogether and usurping his functions. Briefly described, the modus operandi is to convert the wood fibre into cellulose, and then, by a treatment of nitro-sulphuric acid, into nitro-cellulose, after which it is freed from the acid and dissolved in a solution of alcohol and ether, thus forming collodium, which is pumped through glass pipes provided with extremely fine holes, and these collodium threads are passed through warm water (acidulated), which causes the alcohol and ether to evaporate, and only the fine nitro-cellulose threads remain. A number of these fine threads are brought together, slightly twisted and spooled.

This extremely lustrous, but also easily inflammable, even explosive, tissue was put on the market at the time of the Paris exposition, in 1889. Owing to its great liability to catch fire, it did not come into practical use for some time; but since this difficulty was overcome by removing the nitro group (a process called denitrating), the improved fibre has been employed to a limited extent.

Lastly, however, in 1898, a method was invented by Dr. Felix

Fremery and Civil Engineer Urban, of Crefeld, Germany, in which the use of the objectionable nitro-cellulose is omitted. These two inventors dissolve cotton waste in copper oxide of ammonia, and pump this solution through fine tubes. The delicate threads are passed through diluted acid, which separates the copper and ammonia, the result being an extremely fine, lustrous fiber, which is employed as an imitation silk. This process, patented in Germany and in all other civilized states, is said to have the following great advantages over those of Chardonnet and Lehner:

(1.) That the manufacture, as well the the product, is in no way dangerous.

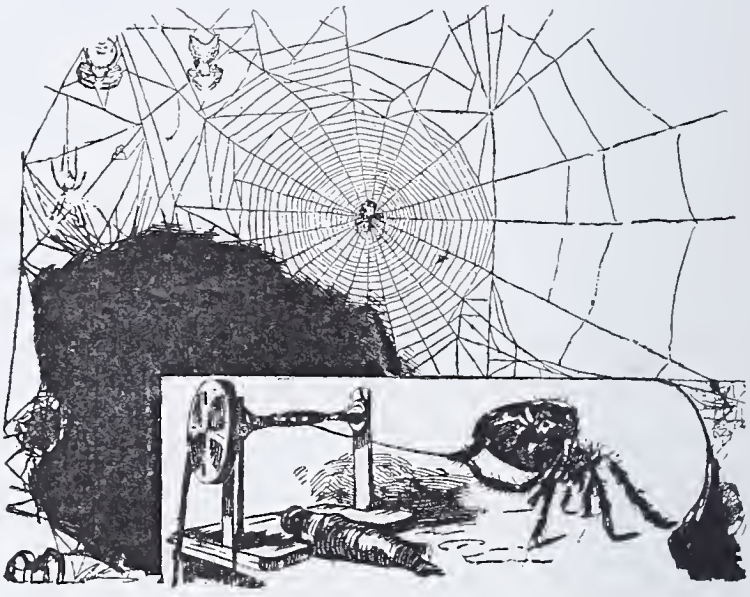

Figure No. 9. Silk Producing Spiders. (See Page 25.)

(2.) That the production is much simpler.

(3.) As a consequence, that imitation silk can be manufactured by this process at considerably less cost.

The United States consul at Bremen, Germany, Max Bouchsein, reported exhaustively on this process near the close of the past year.

Another and cheaper substitute for silk is "Vanduara," which is made from glue or gelatine, as to which it is claimed that one man operating an automatic machine can turn out, in ten hours, 480,000 yards of "silk" equal to the produce of 24,000 cocoons. Then there is a so-called silk, cheap and strong, made from mercerized cotton, by use of caustic soda, after the formula of Joseph Mercer, of Bradford, England, an article that is coming largely into use. But the finished product "looks like thirty cents," as compared to the lustrous fabric resulting from the filament of the renowned Bombyx family, who, despite all competition, are "still doing business at the old stand."

FIG. 8. Putting the Silk into Hanks for Shipment. (See page 23.)

THE SILK INDUSTRY—FROM FIBRE TO FABRIC.

The preparation of the ordinary raw silk for the loom is called "throwing," and about a dozen distinct processes are involved in this branch of work, the product being "singles," "tram" and "organzine," respectively. The first named is formed by merely twisting the raw silk; tram, or woof of the fabric, is obtained by the union of two or more threads of raw, slightly twisted; organzine, usually employed for the warp, is the result of two or more singles to which a harder twist is imparted.

As serving to show the labor involved in silk manipulation, we may say that a thread of ordinary sewing silk may contain 200 threads of the original worm filament as it came from the cocoon, and also that more time is required to "build" a spool of silk than to build an ordinary locomotive.

To illustrate more clearly the tedious processes of preparing the silk for the loom, they are placed in their proper order, as follows:

For Organzine.	For Tram.	For Both Organzine and Tram.
Assorting.	Assorting.

Figures 10, 11 and 12 show examples of the modern winding, spinning and doubling frames, respectively; Figure 13, a quilling machine; Figures 14 and 15 views of the interior of a throwing factory. Figure 16, view of a soft or dyed silk winding room.

We may remark just here that the wages paid in the throwing

branch are lower than in any other, the processes being so simple in the main that any half-grown girl or boy of fair intelligence can learn very quickly.

In regard to the machinery employed, a tremendous advance has been made within the past twenty years. Prior to the introduction of the Atwood system of throwing machinery, the speed of spindles did not exceed 3,000 to 5,000 revolutions a minute; the Atwood

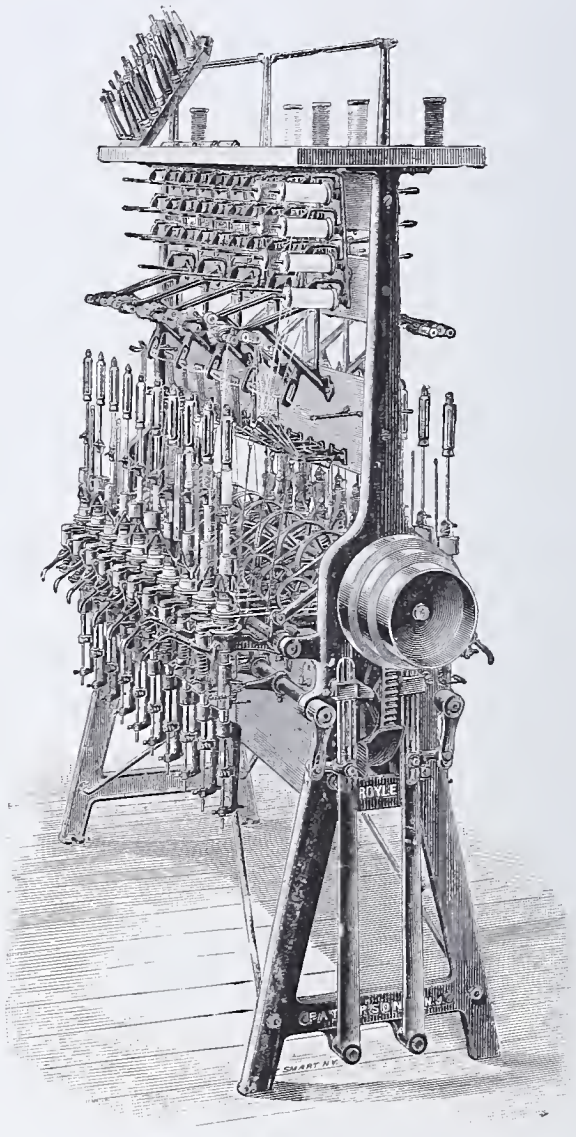

Figure No. 13. Quilling Machine. (See Page 27.)

machine at once increased this to 10,000 revolutions, and since then a speed of 12,000 to 15,000 and even more has been achieved. A veteran throwster even talks of 20,000 to 25,000 revolutions as being possible, but admits that the resultant product would not be satisfactory if spindles were speeded to that degree. In the Italian system of throwing, which is a very slow process, the heavy wooden

FIG. 10. Soft or Dyed Silk Winding Frames. (See page 27.)

Figure No. 17. Interior View of a Silk Dye Works. (See Page 30.)

Italian frames are used and very superior yarns are made—for special purposes.

In each process the silk passes toward the loom—excepting only the dyeing—imperfections in the thread cause of loss of time, money and material. A stoppage of the machinery to reunite a broken thread is a serious matter. "It costs," remarked a veteran manufacturer, "fully five times as much to tie a knot in this country as it does in France." Hence, the careful sorting and "dramming," or weighing. "Picking" consists in spreading out every thread of a warp on a slowly moving frame, so it can be inspected separately for the removal of all lumps, knots or inequalities of any sort. For this work the trained eye and the deft finger are indispensible.

The dyeing is a most important branch of silk manufacture. This may be done, either in the skeins or in the piece. Much the greater proportion of the goods produced in this country are skein-dyed, and we have still to glance at the processes in this department before we are ready to bring our threads of reeled and thrown, or spun, silk to the loom to be fabricated into the many beautiful stuffs which are the completed products of the industry.

Black is always a leading color—if it is a color—but the great variety of colorings and shades is now a chief feature in dyeing silk. In the earlier years the range of tints was very narrow, but since the dyeing has come within the domain of science, the purity, brilliance, delicacy and variety in the tones produced are almost incredible. This infinite, almost endless variety of hues is largely due to the vast improvement in the use of aniline dyes, which are now utilized to produce any tint, shade or color that may be desired.

Many of the more brilliant shades are naturally fugitives, but this difficulty also has been overcome almost wholly by the discoveries of chemists who apply themselves exclusively to the various problems of the color shops in leading dyeing establishments. Some of their achievements in combining color are truly marvellous, one leading dyer exhibiting the solar spectrum in colored silk with striking effect, upward of 100 shades being used.

It is claimed, probably with truth, that the dyes and chemicals imported for American shops are of the very highest quality, much superior to what are used in Europe. As to weighing, with excess of material, let us not suppose our dyers are ignorant of the art. If the manufacturer wants loaded silk he can have it to order.

A variety of material is used for this purpose, including tin crystals and various metals in solution, all of which, used in excessive quantity, have the effect of rotting the fabric and bringing discredit upon the manufacturer. But these deleterious substances impart weight and apparent body to the cloth and the fair customer thinks

she is getting a great bargain in silk, when, in fact, she is buying mostly tin.

Pure water is a sine qua non in silk dyeing, and this being found of a very superior quality in Paterson, it has done much toward making that city the chief centre for custom dyeing, though several Pennsylvania towns also can boast of well-equipped dyeing establishments of the first importance, an interior view of one of these latter being presented in Figure 17.

Whether the weaving is to be done by hand or power loom, the next step after the silk is returned from the dyer is to make the warp. If the warp is intended for the dress piece to contain 5,000

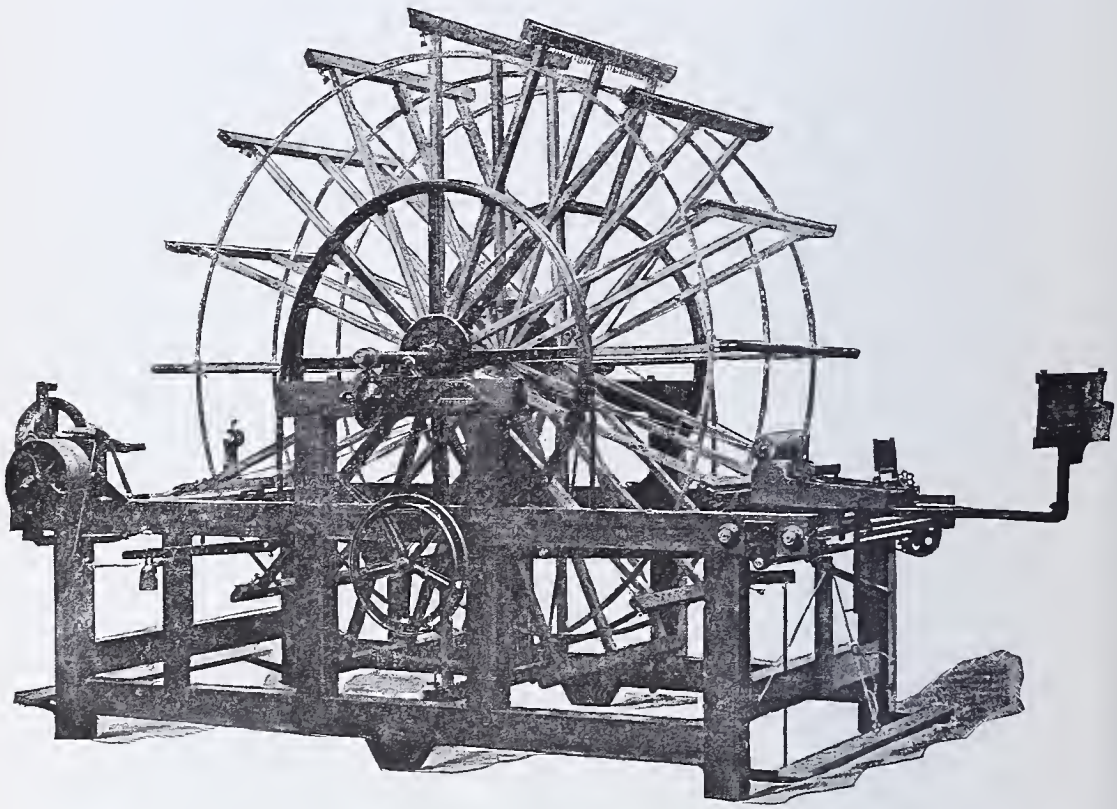

Figure No. 18. A Silk Warper.

threads, 200 spools are arranged on steel wires or pins, on which they are to revolve as the threads are drawn off, all of which are placed at appropriate distances in an upright frame called a creel. Opposite this, about two or three feet distant, stands the "mill," a wooden frame cylinder about seven feet high, and from five to ten yards in circumference. (See Figure 18.)

This revolves on pivots and is turned by a crank, at the convenience of the warper. The ends from each spool are passed through 200 eyelets, forming a part of a piece of mechanism called a "jack," which divides the threads and guides them on the cylinder or warping "mill," where it revolves. The jack is affixed to an upright beam situated

FIG. 11. Hard or Raw Silk Spinning Frames. (See page 27.)

between the mill and the creel, traversing from top to bottom and from bottom to top, the "jack" being drawn up by a cord attached to the upper pivot and let down by the unwinding of the cord.

For a 5,000-thread warp and 200 threads or spools to the creel, it is evident that twenty-five upward and downward motions of the "jack" are necessary before the bulk of the warp has received its full quota of threads. When finished, the warp is drawn from the mill and carefully balled on the hand. The ball is then taken to the picking frame and drawn on a roll and out in sections by a comb-like instrument called a "heck."

The warp is then drawn on the loom-roll, after first having been put through a reed, which is drawn through the warp with rods while being finally picked and wound on the second, or loom roll, and threaded through the heddle, the number of the heddles varying according to the fabric to be woven. This is the plan generally in use for organzine warps, though some manufacturers have adopted new and labor-saving machinery for the purpose. The above is the process, whether the weaving is to be performed by hand or power loom, and whether the product is to be plain, twilled or figured, by means of the Jacquard.

It is unnecessary to go into a minute description of the various looms in use for silk weaving. The old hand loom (see Figure 19), which was formerly heard making its peculiar clatter in so many Paterson homes, is one of the oldest, simplest and most widely used piece of machinery in the world. It was known in almost its present form to the Egyptians and Persians, and in India and China, in which latter country it was used more than 4,000 years ago. There is even a statement to the effect that it antedates the flood.

The upright posts, the different sets of treadles, or harness, depending from the cross-beams above, through the loops or eyes of which the threads of the warp are passed; the roller moved by a crank, around which the warp is wound, and a second roller to receive the goods; the shuttle, which, with its bobbin, carries the thread of the weft or filling; the swinging bar, the reed which brings each thread home—"beats it up"—and the treadle which depresses alternately the sets of harness—who has not witnessed the operation of this simple machinery? It is understood, too, by most that the figure woven depends upon the number of treadles and the arrangement of the warp, and that for particular figures there is needed a special harness and a variety of shuttles. Figure 19½ shows interior view of a Japanese workshop.

In the invention of the power loom (see Figure 20), the questions to be solved were to make the processes of the old hand-loom automatic, exact and rapid; to obtain tenseness in the warp, to effect its gradual unrolling and the rolling up of the woven goods; to drive the shuttle

back and forth at the proper time; to beat up the tissue properly; to effect the stopping of the machinery for the substitution of a new-filled bobbin when needed; and, above all, to accomplish ten or more

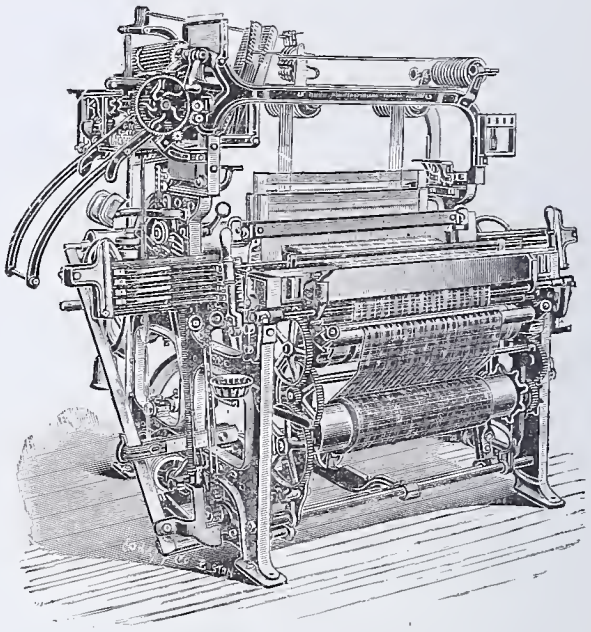

Figure 20. Power Loom. (See Page 31.)

times the work of the weaver by hand within a given period. All this has been achieved abundantly.

The many improvements recently made permit the weaving of

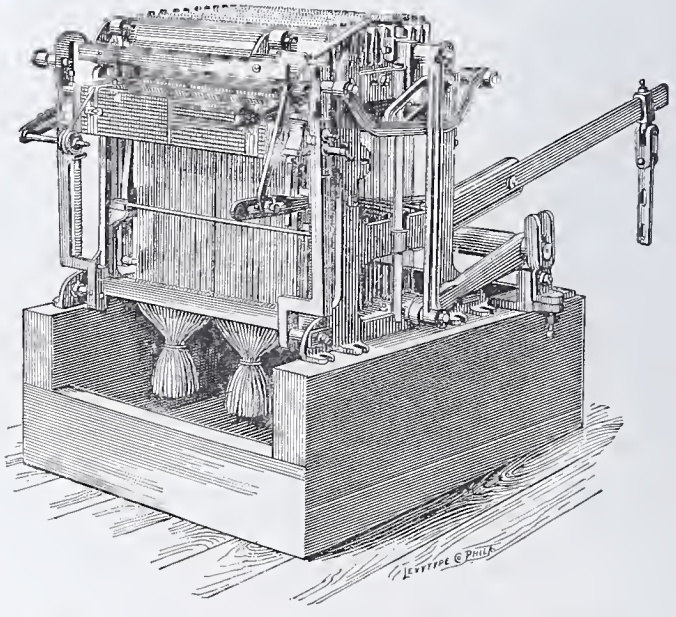

Figure 22. Jacquard Attachment. (See Page 33.)

almost any class of goods on power looms and the hand loom, even in Europe, is now employed only in the production of some of the most elaborate weavers. In this country there is scarcely one left

FIG. 12. Soft or Dyed Silk Doubling Frame. (See page 27.)

in operation, hundreds having been relegated to the scrap heap within the past few years.

What is usually known as the "Jacquard loom" is not really a loom, but an attachment to one, and can be adapted to any. Joseph Marie Jacquard (see Figure 21), was a Lyonnaise, a weaver, and exceedingly poor. After the French Revolution, inventive talent was fostered, and he, employed by a Lyons manufacturer, improved the then existing machinery with a view to substitute mechanical device for the labor of draw boys in making figured goods, the boys being required to maintain a position so unnatural and constrained that in a few years their health was ruined. The invention was not perfected before about the year 1800, after ten years of labor.

Jacquard made no attempt to obtain the reward offered by the London Society of Arts for such an invention, and after showing it to a friend put it aside, and for some time it was forgotten by him. To his surprise, he was one day sent for by the Prefect of the Department, who inquired about the machine and requested him to make another, the original having been lost or destroyed. This he did, and a few weeks later he was summoned to Paris and introduced to Bonaparte.

"Are you the man," asked Carnot, then Prime Minister, "who pretends to do what God Almighty cannot do—tie a knot in a stretched string?"

Jacquard answered that he could do, "not what God could not do, but what God had taught him to do." He explained his device to the Emperor, who rewarded him with a pension of a thousand crowns, gave him employment in the Conservatoire des Arts, and while thus enabling him to exercise his ingenuity in other ways, encouraged the adoption of the excellent Jacquard loom.

That, however, was almost more than imperial patronage could effect. The Council des Prudhommes, who are appointed to watch over the interest of the Lyonnaise trade, broke up this machine in the public place. "The iron (to use Jacquard's own expression) was sold for iron, the wood for wood," and he, the inventor, was delivered over to universal ignominy. Afterward the Lyonnaise were glad to adopt the Jacquard, and two years later the government bought his invention. (See Figure 22.)

Another appliance of more recent invention, known as the "dobby," is of great importance in the higher class of shaft work, since, by its use, a wide variety of "plain effects" can be achieved, such as stripings of all kinds, but not figures, properly so called. (See Figure 23.)

It is estimated that about one-third of the total output of domestic silk goods consist of ribbons, in which department of the industry the highest wages have always been paid to weavers. In fact, the weaving of ribbons, which, up to within a comparatively few years,

was largely done on heavy German, Swiss or French looms, operated by men only, was regarded almost as an art industry, in which males only could achieve satisfactory results.

Consequently the guild of weavers was a power whose demands no manufacturer dare resist, with the result that exorbitant wages were paid for the work, which was done exclusively by the piece, the minimum being about $40 a fortnightly "pay," the maximum reaching as high as $75 and $80 a "pay," in case of the best weavers, employed on the finest class of work.

But this is all passed, or, more correctly stated, is passing. The power of the guild is greatly broken since the modern high-speed, light-running ribbon loom, with automatic "let off" and all the latest improvements has been generally adopted for almost every class of production, save only the very richest qualities and high novelty weaves for which the old heavy looms or more complicated modern ones are used and male weavers employed as operators. But not at the old rate of wages; this has been cut nearly or quite one-half. As for the modern loom, as shown in Figure 24, it is operated easily by young girls of sixteen and upwards, who run two looms for from $12.00 to $15.00 per week. Figure 25 shows the interior of a ribbon weave shop.

The dyeing and printing of silks in the piece is a branch in which remarkable improvements have been made by the domestic piece dyers and printers, a number of extensive and thoroughly equipped establishments being devoted to this class of work in Paterson, N. J., and elsewhere. The materials are usually pongees and various unbleached, or "ecru," silks "in the gum," taffetas, foulards and other weaves. In former years the cheap imported stuffs that were to be printed were treated almost exclusively by Lyons printers, who excel greatly in the art, but for some years past the domestic printers, who impart anywhere from one to seven, or even more, colors, and understand the art of "fixing" them, are doing about all the work for the American market, and are turning out some rarely beautiful goods, the figures being engraved on copper rolls, or cylinders, whence they are removed when the pattern is no longer wanted and others are substituted.

Printing upon the warp before weaving to produce the peculiar blurred or chiné effect, is an important feature of the business, and our print works are turning out some exquisite work of this character.

However, the silk fabric may be treated, whether the weave be plain or figured, the finishing is always of importance and forms a separate department. The fabric is subjected to a number of processes, is passed over hot rolls, or calenders, and, if required, is watered during one of the processes.

Beyond this there remains only the measuring and folding, which,

FIG. 14. Winding Room in a Hard Silk or Throwing Mill. (See page 27.)

in these days, is done at one and the same time, automatically, by an ingenious machine highly perfected and thoroughly accurate. See Figure 26. Figure 27 shows the interior of a modern "weave shop."

Apart from broad goods and ribbon production by far the most important feature of the domestic silk industry is the manufacture of threads, button-hole twist, including sewing machine twist, knitting and crochet silk, embroidery and art silks, floss, etc., the great bulk of which is made in the New England states. In this branch our domestic makers have long excelled, have "beat the world," in fact, so that not only is there no import of these goods, but there is a very considerable export for several years past, and the volume is steadily expanding.

THE SILK INDUSTRY.—OUTLINE HISTORY.

Both the silk worm and its food plant, the white mulberry tree, are native products of Eastern Asia. All available data agree that China was the cradle of silk in a very remote epoch. So far as can be learned, silk, in point of age, stands about midway among the textile fabrics, wool and flax having preceded it, while cotton, hemp and other fibrous plants followed it somewhat closely. The exact date when its use was discovered is somewhat uncertain, it being variously placed at 1,650 to 1,700 years before Christ. From this the deduction is that Hoang-ti, Third Emperor of China, contemporary of Joseph, the son of Jacob, must have been the first silk culturist and that it is, therefore, an industry of royal birth, ennobling all in anywise engaged therein.

The tradition, as found in the Chinese work Hoai-nan-wang, is that this Chinese Emperor, desirous that Si-ling-chi, his legitimate wife, should contribute to the happiness of his people, charged her with the cultivation of the silk worm and the testing of the practicability of utilizing its product. In this, the royal silk operative was eminently successful, not only raising large numbers of the worms but learning to reel the silk and make it into garments. The Empress has accordingly been deified under the title of "The Goddess of silk worms," and to this day the Chinese celebrate every year the con-con feast in her honor. This occurs at the beginning of the silk season, and the Empress of China still, after the lapse of 3,600 years, offers sacrifices to her illustrious predecessor. Immutability is a feature of the Central Flowery Kingdom.

The secrets of silk production were most jealously guarded by the Chinese, and it was a long time in reaching Europe, some holding that it was not known there until the fourth century before Christ. Of this early period the statement is that woven stuffs, made in China, were sold at such a fabulous sum that the fabric cost, ounce for ounce, its weight in gold. For a long time after the first discovery of its uses the Chinese forbade the exportation of raw silk or silk worms' eggs under penalty of death.

Nothing, however, could prevent the westward march of His Wormship. All silken fabrics were in great demand in profligate Rome, even at their then tremendous cost, but the Emperor Tiberius prohibited their being worn by men, declaring it a mark of effeminacy, and the satirists of that day inveighed against the wearing of the transparent silken tissues then produced, on the ground of indecency. In A. D. 222, the debauchee Heliogabalus scandalized his people by appearing in a garment made wholly of silk. In A. D. 273 the Emperor Aurelius refused to procure his Empress a silken robe because of the extravagant price and the bad example. Doubtless she pouted or sulked over the refusal as several millions of her sisters have since done when denied a coveted silk.

The introduction of silk worms into Japan is said to have taken place in the second half of the third century of our era. The tradition is that Corean and Chinese immigrants brought them over from the continent and first taught the Japanese their use. The silk industry, it will thus be noted, obtained a footing and spread through the island-empire contemporaneously with tea culture and Buddhism, and, like these, through the agency of Japan's nearest neighbors.

The Japanese peasantry, however, have a pretty legend that gives an altogether different account of the affair. According to it, a beautiful princess of India was placed in the hollow trunk of a mulberry tree by her cruel stepmother and sent adrift upon the sea. The gods, in compassion, caused the floating trunk, with its precious burden, to be borne by wind and wave northward to their well-beloved Japan. The princess was driven upon the coast of Hitachi, where the people of Toyo-Ura received her kindly. Here the tree took root and grew and multiplied until Hitachi was filled with mulberry groves, and upon the death of the beautiful princess, the gods, to reward the hospitality of the people, changed her body into a silk worm, and from the transformed Indian princess and her mulberry tree boat has sprung the silk industry of Japan.

In the year A. D. 552, two Persian monks who had lived in China as missionaries and had learned of the silk worm, succeeded in conveying a large number of eggs, concealed in hollow canes or "palmers," staves, to Constatinople at the peril of their lives. These were hatched and formed the nucleus of the industry there, the monks

FIG. 15.—Spinning and Reeling Room in a Hard Silk or Throwing Mill. (See page 27.)

revealing all that they had surreptitiously learned while in China of the care of the worm and the manipulation of the product.

Coming down to a later period we find that in A. D. 877 the rebel Chief Baichu captured Confu, the chief centre of the Chinese silk industry, put to death all its inhabitants, among them 120,000 silk manufacturers and merchants, destroyed its mulberry trees and silk worms and left the industry to grow in Western Asia and Eastern Europe, where it had become firmly established.

The silk worm made slow progress, however, in Europe. In the year 910 he made his appearance in Cordova, Spain, brought there by the Moors, and in the tenth and eleventh centuries the silk manufactures of Spain and Sicily were extensive. King Roger, first Norman King of Sicily, invaded Greece in 1146 and carried off the silk treasures of Athens, Thebns and Corinth, and took captive a large number of silk weavers and with his booty established more firmly the industry in his kingdom. From Greece and Italy the industry passed to Marseilles and in the fourteenth century it was introduced into Avignon.

Under Henry IV, Sully established a silk worm nursery in the garden of the Tuileries. Louis XIV also encouraged the industry in his time. During this time the weaving of silk fabrics with foreign threads had developed greatly. There were beginnings of the manufacture at Tours, and perhaps at Lyons, as early as the thirteenth century. It is said that the first white mulberry tree planted in France was brought by St. Aubon, a valiant knight, on his return from the Second Crusade.

The silk industry was never so developed as during the reign of Louis XIV, in whose time, it is stated, nearly 400,000 Huguenots were engaged in it. When the "Grand Monarch" turned fanatic and revoked the Edict of Nantes, these were all exiled and the industry was nearly annihilated, the 18,000 looms of Lyons being reduced to 4,000 and the 11,000 of Tours to 1,200. The mills were reduced in number from 800 to 70. Of these Huguenot refugees over 100,000 went to England and established the silk manufacture on a firm basis. This was the first recorded appearance of His Wormship in England. The refugees also carried the industry to Germany and Switzerland, and all these countries soon became formidable rivals of France in this branch, which languished there up to the close of the last century, it having just begun to recover when it was again destroyed by the Revolution of 1793.

All attempts at silk culture (the production of cocoons), in England had failed, the climate being unfavorable to the silk worm, until after the introduction of the Italian method of throwing or twisting, in 1718, through the daring enterprise of John Lombe, a mere youth. Prior to this, very little had actually been accomplished. In the

time of the magnificent Henry VIII, he could scarcely obtain a pair of silk stockings for gala occasions. His daughter Elizabeth was presented with a pair of English black silk stockings as a remarkable gift.

In 1585 some silk manufacturers had come to England from Antwerp, which gave the business a slight impetus. James I encouraged the industry and some throwsters, dyers and weavers were brought from the continent and, in 1629, the "silk throwsters" of London were incorporated, the trade having its dye called "London Black." In 1661 this organization employed 40,000 men, women and children. It was in 1685 that the Huguenot exiles from France arrived and established such seats of manufacture as Spitalfields, producing silk fabrics of the best styles then known anywhere.

One great difficulty, however, the English silk manufacturers had always to contend with; they were compelled to purchase their thread, or yarn, abroad, as all the material was formed into threads and twists on the continent. In 1702 a Mr. Crotchet had attempted to start a silk throwing mill but had failed, and it remained for John Lombe, whose name is still remembered with veneration—inasmuch as he not only introduced this important feature into the country, but lost his life by so doing—to succeed in that in which so many had failed. He resolved to visit Italy and learn the processes of silk throwing at whatever cost, and this he did, starting in 1715.

He found great difficulty, however, for the Italians guarded their secret most jealously. At Piedmont, finding the silk machinery closely watched, he gained admission through the connivance of the work-people in the disguise of a common workman, making several secret visits and carefully noting down everything, even to making sketches of parts of the machinery. He was discovered before he was nearly ready to go home and was obliged to fly for his life, carrying with him his notes and sketches. He would have been assassinated had he tarried another hour. He took refuge on board a ship and escaped to England with his priceless acquisition, accompanied by two Italian workmen whom he had bribed and who risked their lives in following him.

Arriving in England, he leased an island in the river Derwent at £8 per annum and built a mill at a cost of £30,000, still standing and known as "The Old Silk Mill." While the mill was being erected the business of silk throwing was successfully inaugurated, and in 1718, Lombe received a patent for fourteen years. It was found that the thread could be produced vastly cheaper at home than imported from abroad, and as this enabled English manufacturers to compete with the French and others this was really the most important epoch in the history of the silk industry in England.

John Lombe did not live long to enjoy his prosperity, for soon

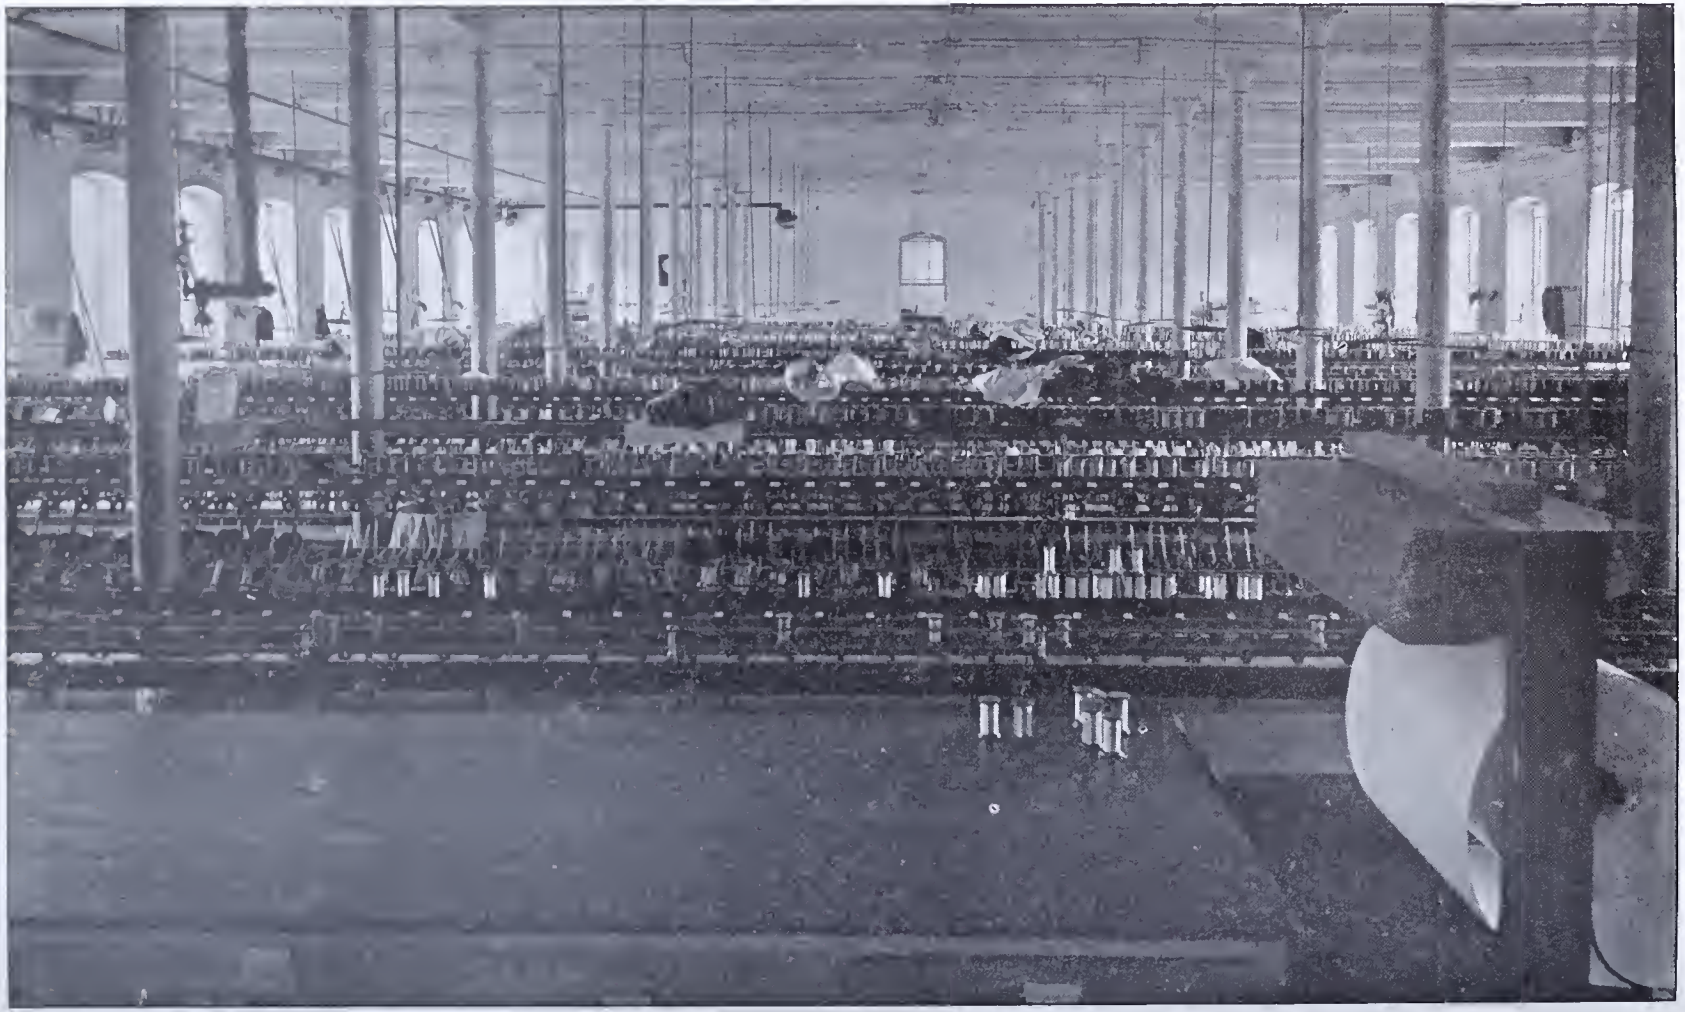

FIG. 16. A 2,400 Spindle Soft or Dyed Silk Winding Room. (See page 27.)

after his mill was fairly in operation he died, at the early age of twenty-nine, from poison administered by the two Italian workmen from whom, to a large degree, he had learned the art. The story of Lombe's fate is very curious, but well authenticated. It is to the effect that the Italians, in their own country, finding that they had been outwitted and that their lucrative trade was endangered, sent over a female poisoner to take his life, if possible. This woman entered the mill as a workwoman, endeavored to gain over her countrymen and succeeded, a slow poison being administered to Lombe that finally resulted in the death of their victim. The Italians then fled to their own country. Grand funerals were then in fashion, and the most superb known in that day was the funeral of John Lombe, who fell a victim to his ambition to introduce a new branch of manufacture for which thousands upon thousands have since had cause to bless his memory.

The patent was not renewed after fourteen years and soon the silk throwing business was followed in many parts of England. A picture of this first mill represents an immense establishment, four stories in height, one-eighth of a mile in length, and the grand machine is said to have been constructed with 23,586 wheels and 96,746 movements, which worked 73,726 yards of organzine with every revolution of the water wheel, and as it revolved three times per minute, the almost inconceivable quantity of 318,504,960 yards of organzine was turned out daily. Hutton, however, who worked for seven years in this mill, reduces the number of wheels to 13,384.

In 1860 there were 400 silk throwing mills in England, employing about 100,000 hands. Owing to various causes which need not be enumerated here, it was only by the most rigid protective measures that the silk manufactories of England were sustained, even with all the great improvements in machinery and the vast amount of capital invested; and when, in 1860, the commercial treaty of that year admitted French silks duty free, many branches of the silk manufacture of Great Britain received their death blow, reducing the silk weavers of Manchester and the Macclesfield to beggary by the thousands—a lesson in the value of protection that is not likely to be needed in this Commonwealth. These two great centers of the silk industry, formerly competed with Lyons for the American trade, but at this time the competition ceased. Only about forty years ago silk goods of all kinds imported to this country were drawn about equally from England and France; to-day, we buy no silk from Great Britain worthy of mention.

The duties on silk fabrics abrogated by the Cobden treaty were not heavy, yet they had been sufficient to prevent ruinous foreign competition. As an effect of their abrogation thousands of the looms and spindles of the great mills referred to, purchased at a

merely nominal price, were brought over and set running in Paterson and other American mills. The business has, in fact, been largely transferred to this continent, whither the reader is invited to follow it.

The Spanish conquest of Mexico was the means of introducing the silk industry to this continent. We may dismiss the vexed question alluded to by Prescott as to whether the Aztecs made fabrics containing silk. Humboldt declares that the material they used was not the product of the Bombyx mori. Herrera asserts that there was no silk and Acosta, and that there were no mulberry trees in the Indies prior to their introduction from Spain. The voluminous work of Hernandez, published in 1607, gives full accounts of the plants and animals of the new world, and does not mention the silkworm or the mulberry.

In the year 1522, Cortes, as ruler of New Spain (Mexico) prepared a plan for its government; the details included the appointment of officials in charge of the silk industry, the first step toward which was the planting of mulberry trees. The record of certain legal proceedings has secured to history the date of the introduction of the silk worm into America. After Cortes withdrew from personal rule in New Spain, the authorities who were placed in charge by the King made an investigation of what had been done by the board of auditors who preceded them. This was in the year 1531. Among the items of this procedure is a statement that a quarter of an ounce of silk worm seed (eggs) was sent on public account from Spain to Francisco de Santa Cruz, a citizen of Mexico.

The seed arrived in safety and was placed by Francisco with Auditor Diego Delgadillo, who was a native of Granada, and presumably knew something of silk culture in his own country, where it was introduced by the Moors as already stated. Delgadillo made use of the eggs and the experiment was eminently successful.

This was the beginning of an industry in the culture of silk, its manufacture into woven goods, including the now popular taffetas, one of the oldest of silken weaves, which has not generally attracted the notice of modern writers on the subject. But by the end of the sixteenth century this manufacture had almost wholly ceased.

So far as silk culture is concerned, however, the industry was, after a short interval, to reappear on this continent and unfold itself in the sunshine of royal favor. This came about through the jealousy by England of France, her ancient enemy.

The industry was established in France, as heretofore stated, and made notable progress, as to both culture and manufacture. It soon excited the envy of James I, of England, and he proceeded to copy, even in details, the performance of Henry of Navarre, and selected the American colonies as the most promising field of operation. In

FIG. 19. Old Hand Silk Loom. (See page 31.)

fact, however, nearly a century elapsed after their introduction by the Spaniards in Mexico before silk worm eggs were again brought to this continent from Europe, and King James supplied the "seed."

The undertaking met with delay at the outset. The expedition of Sir George Summers, with a fleet of seven vessels, bound for the shores of Virginia in 1609, suffered shipwreck and disaster. Two vessels were lost entirely; the rest were driven by storm to the Bermudas. A part of the expedition ultimately reached Virginia, but brought no silkworm eggs. This was two years after the settlement of Jamestown.

For some years subsequent to this the colony was in a forlorn condition, but in 1619 great efforts were made for its relief. Silk culture appears prominently as among the means to help the people out of their poverty and the following is recorded as one of the items in a sort of invoice described as "A Note of the Shipping, Men and Provisions sent to Virginia by the treasurer and company in the yeere 1619:"

"Silke; for which that country is exceeding proper, having innumerable store of Mulberry trees of the best, and some silkworms naturally found upon them, producing excellent silke; some whereof is to be seene. For the sitting up of which commoditie his Majesty hath been graciously pleased now the second time (the former having miscarried), to bestow upon the Company plenty of silkwormes seed of his own store, being the best."

Sending out silk worm eggs from England was followed in 1622 by the most peremptory and urgent directions to encourage silk culture. Aid was promised on the one hand to colonists who entered heartily into the work, and on the other hand punishments were ordered for those who neglected the matter. In 1623 the legislature of the colony issued further orders requiring mulberry trees to be planted, the fine for neglect being twenty pounds of tobacco. The act also offered a premium of fifty pounds of tobacco for every pound of reeled silk produced.

At this point we can give what is probably the earliest quotation for raw silk in this country. It includes also the price of cocoons, here described as "coddes" and elsewhere as "bottomes." Too much stress should not be laid upon the accuracy of the record, as it was put in print nearly thirty years after the period to which it refers.

The traffic could not have been large, but there is other evidence that some silk was made, and we may, in any case, regard the quotations as "offering prices" of that date:

"From a valuation of the commodities growing and to be had in Virginia, valued in the year 1621. And since those Times improved in all more or lesse, in some 1-3, in others ½, in many double, and in some treble:

"Silke coddes, two shillings six pence the pound.

"Raw silk 13 s. 4 d. the pound, now at 25 s. and 28s. per pound.

"Silke grasse, to be used for cordage, 6 d. the pound."

This latter has reference to a fibrous plant (probably ramie) growing wild and extensively in the colony. Queen Elizabeth had a gown made from this material, described as "a substantial and rich piece of Grograine." It was hoped that by cultivation the fibre of this grass could be improved so as to equal the silk which it was said to resemble.

On his accession to the throne, in 1625, Charles I took the government of the colony in his own hands. Very little progress in silk culture seems to have been made during the reign of that unfortunate monarch. Under the Protectorate, interest in the subject was revived, and several curious tracts were written on behalf of the industry. The most noted of these essays were by ("E. W.") Edward Williams (1650). Williams regarded the production of silk as one of the wonders of nature; a mystery, which, if taught to the savages, might impress them with pious awe. A similar idea impressed itself on Samuel Hartlib, who was an enterprising merchant of London, and who has a better chance of remembrance in literature than the other silk essayists of the period, since the poet Milton dedicated to him a "Treatise on Education." The ponderous title to one of Hartlib's books is itself a curiosity:

"The Reformed Virginian Silk Worm; or, a Rare and New Discovery of a speedy way, and easie means, found out by a young Lady in England, she having made full proof thereof in May, Anno 1652. For the feeding of silk worms in the woods, on the mulberry tree leaves in Virginia, who, after forty days' time present their most rich golden-coloured silken Fleece, to the instant wonderful enriching of all the Planters there, requiring from them neither cost, labour or hindrance in any of their other employments whatsoever. And also to the good hopes that the Indians, seeing and finding that there is neither art, skill or pains in the thing, they will readily set upon it, being by the benefit thereof inabled to buy of the English (in way of Truck for their silk-bottomes) all those things that they most desire."

In his introduction, Mr. Hartlib refers to the efforts of King James to extend silk culture in England by planting mulberry trees and rearing silk worms, and then he proceeded to urge that the Indians be pressed into this service, in the hope of converting them to Christianity and making a profit at the same time. The essay overflows with pious phrases and calculations of gain, curiously intermingled.

But it does not appear that the Virginia planters were stirred to much activity in raising silk. Punishments and rewards were alike in vain. An act of the colonial assembly in 1656 imposed a fine of

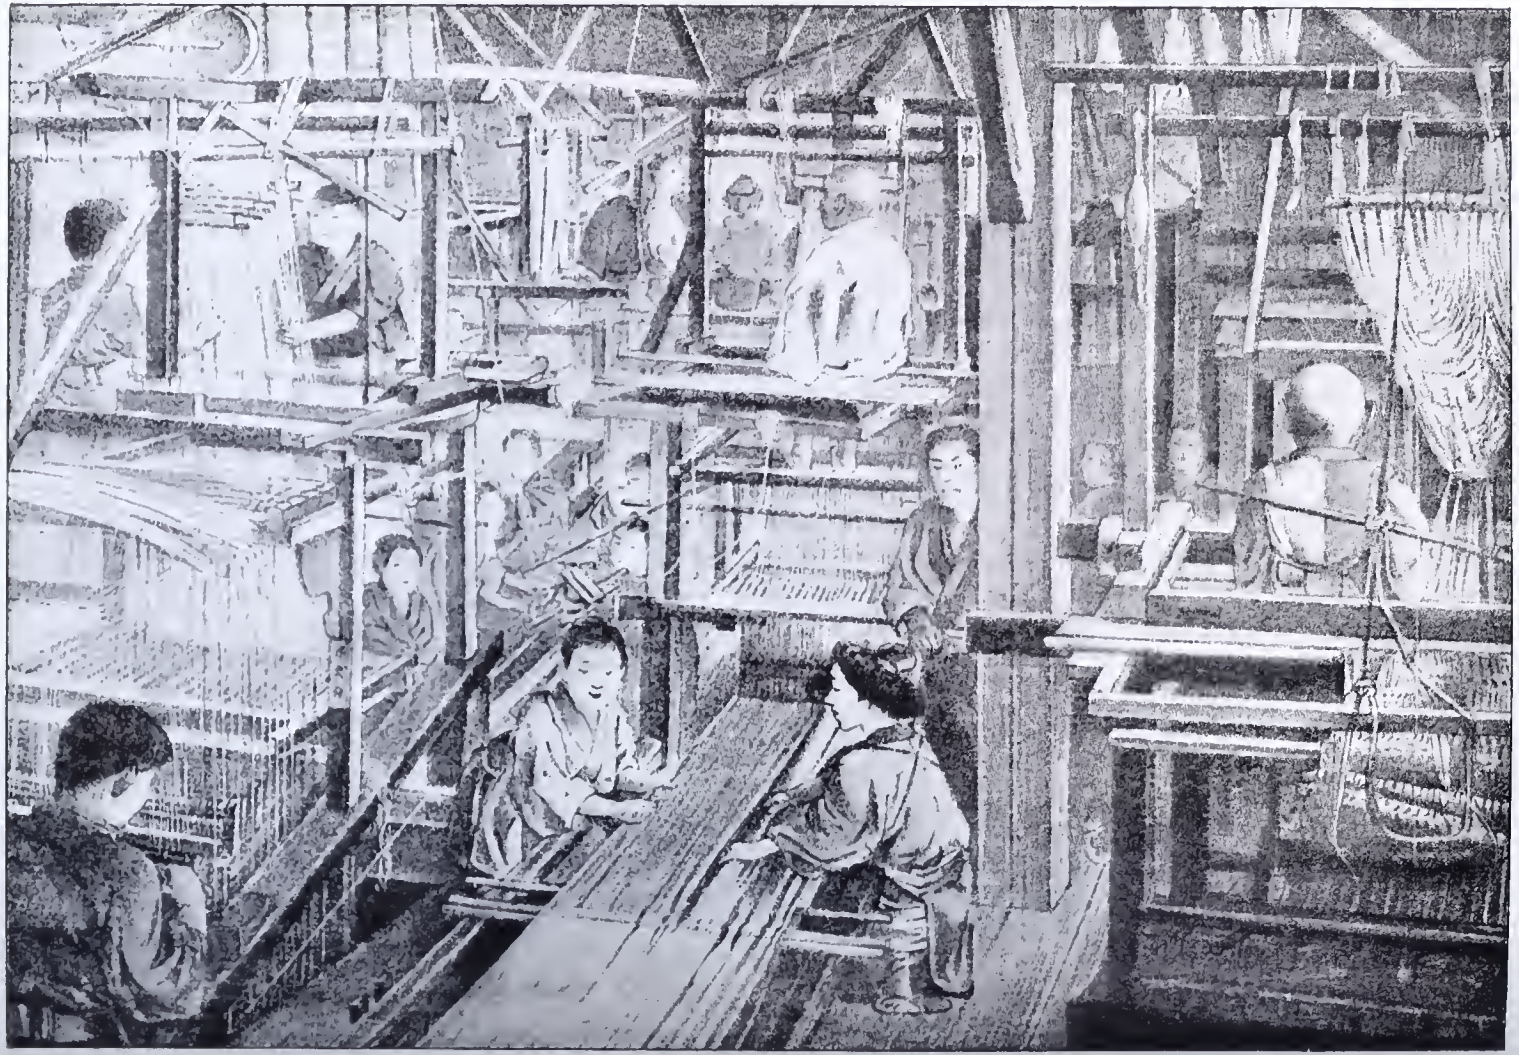

FIG. 19½. Interior View of a Japanese Weave Shop. (See page 31.)

ten pounds of tobacco on any planter who had not at least ten mulberry trees to every hundred acres. A premium of 4,000 pounds of tobacco was given as a reward for remaining in the business of silk culture in the colony. In 1657, 10,000 pounds of tobacco was offered to any one exporting £200 worth of raw silk, and 5,000 pounds of tobacco to anyone producing 1,000 pounds of "wound silk" in a year. But it is difficult to find any record of the product.

There is, indeed, a tradition, treated rather incredulously by historians, that the king, at his coronation in 1660, wore a robe and hose of Virginia silk. There are no records of any further noteworthy production of silk in Virginia, though we are told that "the mulberry tree grows there like a weed, and silk worms have been observed to thrive extremely and without hazard."

During the latter part of the seventeenth century, a large body of French Huguenots settled in the southern part of the province of Carolina. They brought with them a knowledge of various industries, and are probably to be credited with the earliest production of silk mixed fabrics in this country. At about the same period, 1693 to 1702, a vigorous, though restricted, attempt at silk culture was made by Sir Nathaniel Johnson, and the locality of this undertaking bore the name of "Silk Hope" for more than a century. It was strongly urged at this time that the colored people be taught to cultivate silk. This should be of interest to modern promoters of schemes for employing southern negroes in silk raising, since the suggestion of such service as peculiarly suitable for the colored race is thus antedated about 200 years. Joshua Gee, an eminent English publicist, made an estimate that the labor of slaves employed in raising silk would produce about twice as much value as in planting sugar or tobacco. It was also suggested that the mother country should send her paupers and "small offenders" to South Carolina; "it must be a weak Hand indeed that cannot earn bread where silk worms and white mulberry trees are so plenty," urged a writer of that date.

Far more anxiety for silk culture in the colonies was displayed in England than in America. The planters did not take serious interest in the business. A colony of Swiss who settled in South Carolina about 1733-'35, under the leadership of John Peter Purry, of Neufchatel, was successful in raising silk and cotton, and was credited with some progress in manufacture. The mulberry tree flourished in the light and sandy soil of the pine lands. The excellent quality of South Carolina silk was certified by Sir Thomas Lombe, who considered it equal in strength and beauty to that of Italy. But as to amount produced in the Carolinas, the record is that it reached but 251 pounds in the twenty-five years from 1730 to 1755.

In the last named year, Mrs. Pinckney took with her to England

some silk which she had raised and spun near Charleston, and three complete dresses were made therefrom; one was presented to the princess dowager of Wales, one to Lord Chesterfield and one remained an elegant heirloom in possession of the family for more than fifty years. It is said that 630 pounds of silk were raised in 1765 at Silk Hope plantation.

Meanwhile the London Society of Arts was giving handsome bounties for cocoons and raw silk, and kept up the offer till 1772. Parliament, in 1769, granted a bounty of 25 per cent. for seven years on all raw silk imported from the colonies. But the Revolutionary War put a stop to the bounties and the silk industry of South Carolina ceased to exist. The Abbé Raynal has pronounced its funeral oration. That philosophical writer, of course, offers an ingenious theory to the effect that silk was not exported because negresses were not imported. He concludes:

"Yet the progress of this branch of trade has not been answerable to so promising a beginning. The blame has been laid on the inhabitants of the colony who, buying only negro men from whom they receive an immediate and certain profit, neglected to have women who, with their children, might have been employed in bringing up silk worms, an occupation suitable to the weakness of that sex and to the tenderest age."

Tracing the silk industry in the order of its starting at different points in this country, we find it introduced into Louisiana next after South Carolina by the notorius John Law, of "South Sea Bubble" fame. Many mulberry trees were planted in and near New Orleans. Failure to reach profitable results seems, however, to have overtaken every effort and we do not read of any considerable silk product. Favorable soil and climate and a knowledge of the business on the part of the colouists were not wanting, but legislative bounties were.

Georgia, which had been part of the "fertile Carolinas," was made by royal charter a separate province in 1732, and placed in control of a board of trustees. This event became the occasion of an urgent pressure in favor of silk culture. A colonial seal was ordered, containing, on one side, a representation of silk worms. some beginning and others having finished their webs, with the motto: Non sibi sed aliis (Not for ourselves, but for others); but it does not seem to have been meant, by the use of this motto, to suggest that the colonists, in raising silk for British manufacturers, were laboring "not for themselves but for others," though that was the fact.

Late in 1732 a man from Piedmont was sent out by the trustees to teach the colonists the art of reeling. It was an occasion of much congratulation in 1734-'35 when General Oglethorpe took with him to England eight pounds of colonial silk, and showed it to the trustees, who presented it to Queen Caroline. Under royal instructions, Sir Thomas Lombe (to whom allusion has been made on a foregoing

FIG. 21. J. M. JACQUARD, The Famous Inventor. (See page 33.)

page) took charge of the precious consignment, and had it thrown and woven at his factory; so that, in 1735, upon the king's birthday, the queen honored the colony by appearing at a levee in a dress said to be entirely made of Georgia silk.

Several Italians of both sexes were brought to Savannah in 1736 from Piedmont in charge of a Mr. Amatis. The foreigners were proficient in the arts of silk culture and reeling; the men were ordered to teach male English colonists to raise mulberry trees, the women to take English girls as apprentices in rearing worms and reeling from cocoons. "In Italy and in the south of France, young girls carry the eggs in their bosom, and hatch them by their natural heat. In other countries this is done by means of manure or hot-houses." It is not specified which of these processes was taught to the English girls. Some of the Italians behaved badly; one of them stole the reels, broke the copper pans, spoiled all the eggs he could not steal and fled to South Carolina; but a little seed and a few faithful Piedmontese were left.

Meanwhile, a number of Protestants, driven out of their home in the valley of the Salza, Bavaria, had emigrated to Georgia and founded a town, which they called Ebenezer, about twenty-five miles above Savannah, near to, but not quite on the river. They brought with them several useful arts and soon accomplished more in the business of raising silk, with far less fuss, than their neighbors at Savannah. There were notices at this period of a scheme for interesting the Chickasaw Indians in the work of silk culture. English writers were again urging attention to the business. Even the muse was invoked to stir the lagging colonists, and a poem, on the return of General Oglethorpe to Georgia, in 1736, winds up:

> "Nor less the care
> Of thy young province to oblige the fair;
> Here tend the silk worm in the verdant shade
> The frugal matron and the blooming maid."

But as to the export of raw silk, it was admitted in 1740 that "no great entries have been seen of any yet in the custom house;" in fact, the colony of Georgia was at this time in a very weak and impoverished condition, and scarcely able to produce enough of the necessaries of life for its own sustenance. In 1744 but few bounties were offered for silk; a filature was built at Savannah, and the implements for reeling were ordered to be furnished. Bounties were also offered in 1749 for proficiency in the art of reeling, and the trustees supplied the requisite apparatus to competitors. In the following year fourteen young women claimed the bounty and were given permanent employment at the filature, which, by this time, had an outfit of tools and implements.

We are now approaching the period when silk culture in the colonies attained its highest development. An exaggerated notion of

the results has been formed by several of the writers who have recorded them. This is chiefly due to neglect in discriminating between cocoons and raw silk. The records from 1757 to 1768 are mostly of the production of cocoons; and of these articles, when fresh or not specially dried, ten or twelve to fourteen pounds are required to furnish one pound of reeled or raw silk.

An assertion has frequently found place and comment in histories and essays, that, in the year 1759, 10,000 pounds of raw silk were exported from Georgia to England. This arose in an ambiguous, not to say erroneous, publication from Carleston, South Carolina, which Adam Anderson has fortunately quoted in full. He says:

"We had public Advices in this year 1759 from Charles-Town, in South Carolina, of a very hopeful Prospect in that Province of the gradual and considerable Progress and Increase of the Production of Raw-Silk there and in the adjoining Province of Georgia, viz: In the year 1757, 1,052 Pound weight of Raw-Silk Balls were received at the Filature in Georgia; and the next year produced no less than 7,040 Pound weight thereof. And that in this year, 1759, there has been received at Savannah, the Capital of Georgia, considerably above 10,000 Pound weight of Raw-Silk, although the Season has not been favorable."

It will be seen that the foregoing treats of production, not of export, and, therefore, presumably, of cocoons, not of reeled silk. At all events, the facts were so understood by Rev. Jared Eliot, of Killingworth, Connecticut (grandson of John Eliot, the "apostle of the North American Indians"), writing in the very year when the advices were received. His version is as follows:

"By a late account from Georgia, it appears that the Silk Manufactory is in a flourishing way. In the year 1757, the Weight of Silk Balls received at the Filature was only 1,052, last year produced 7,040 and this Year already above 10,000, and it is very remarkable that the Raw Silk exported from Georgia sells at London from two to three shillings a Pound more than that from any other Part of the World."

This seems quite correct, except in calling the business a "silk manufactory."

The policy of raising silk by means of bounties was pushed to its extreme in 1751, when the trustees of Georgia established the following scale of premiums, which has certainly never been surpassed:

For first quality cocoons, 2 s. per pound; if delivered at filature, 3 s. 6. d.

For second quality cocoons, 1 s. 3 d. per pound; if delivered at filature, 1 s. 8 d.

For third quality cocoons, 6 d. per pound; if delivered at filature, 1 s. 1 d.

This was at least two or three times what the cocoons were worth,

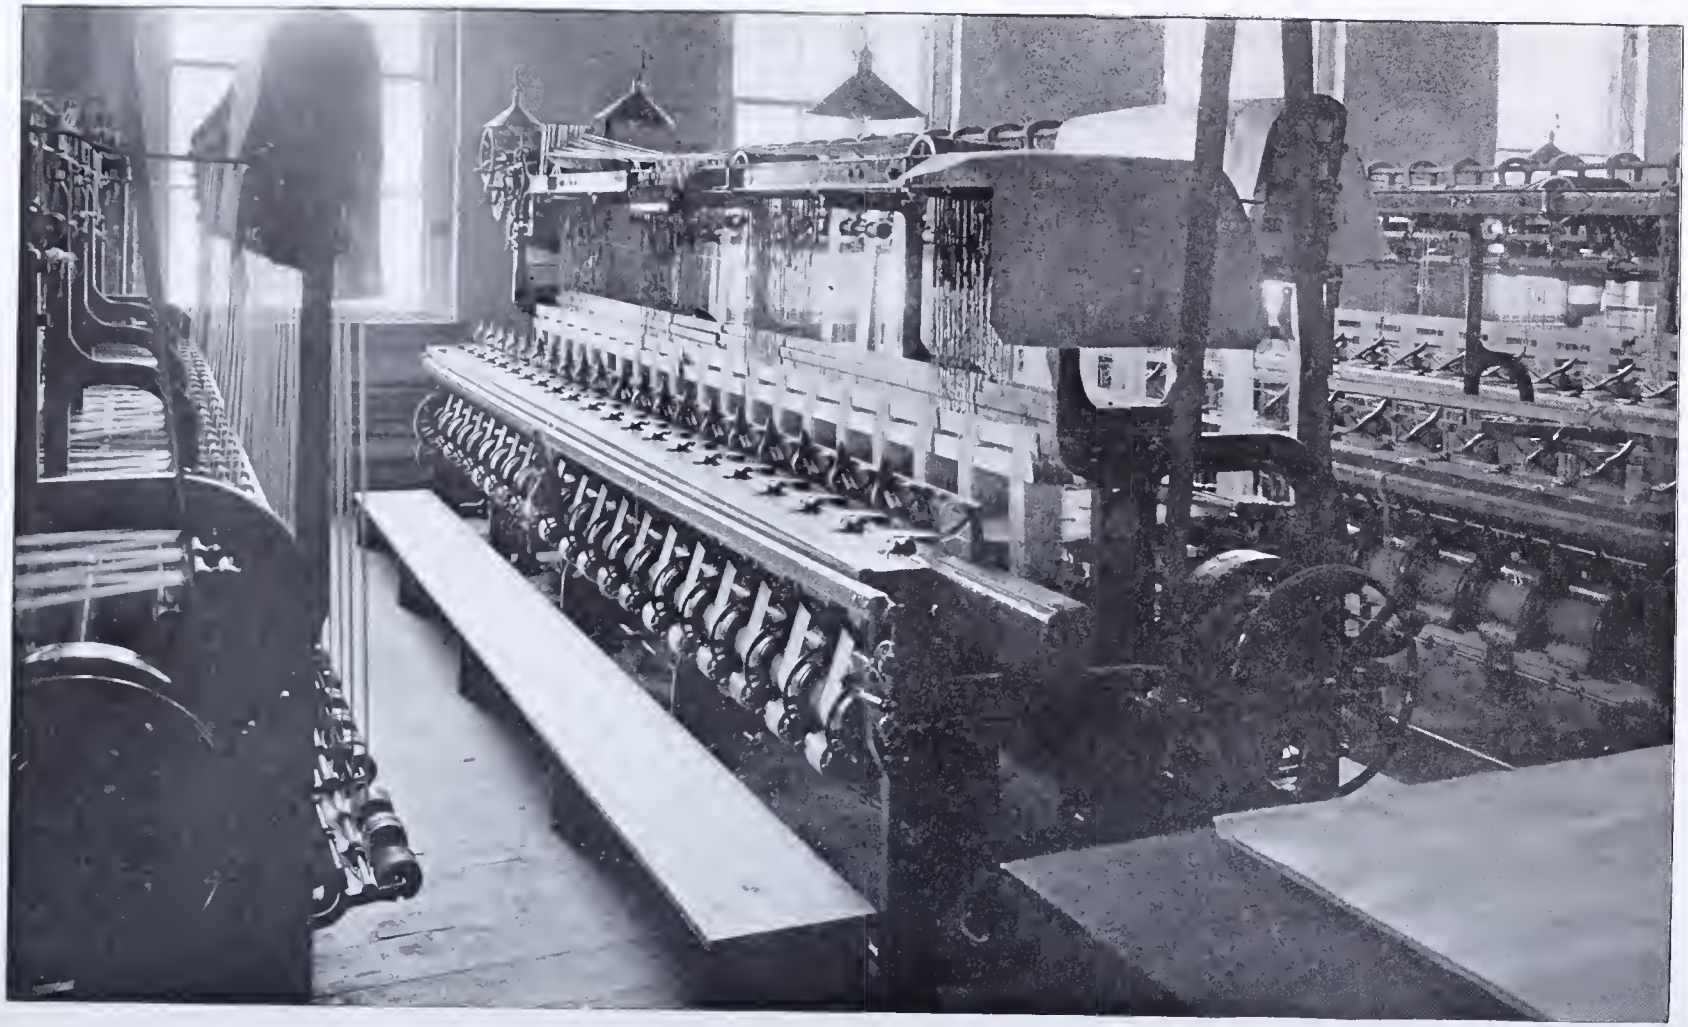

FIG. 24. A Ribbon Loom. (See page 34.)

and is "truly astonishing." The patent of the trustees expired in 1752, and with it all the chartered privileges of the colony, which then became a royal province, directly dependent upon the crown for government. Acts of parliament of almost equal liberality soon replaced the measures of the trustees for spurring the silk industry. These acts were various, and the encouragement they gave was fluctuating. One of them, in 1749, admitted raw silk from the American plantations free of duty, and provided that Georgia and South Carolina should thereafter "have the honor of being denominated Silk Colonies." In the same vain of sweetness, George II, June 21, 1754, directed a silver seal to be made for Georgia, bearing on one side a figure representing the genius of the colony offering a skein of silk to the king with the motto: "Hinc laudem sperate coloni."

The silk product rose while the bounties for delivery at Savannah were most liberal, but sank with marvelous rapidity shortly after their reduction, falling to 290 pounds in 1770. Throughout the entire period of silk culture in Georgia the Saltzburghers of Ebenezer were among the largest producers, and were almost the only ones in the years immediately preceding the War of the Revolution, who prepared raw silk for export. During the war the French settlers at New Bordeaux, seventy miles above Augusta, are said to have supplied "much of the high country" with sewing silk made from cocoons of their own raising. The industry ceased, however, to attract attention; the last parcel of raw silk offered for sale in Georgia during the century being in the year 1790, when over two hundred-weight was purchased for export at prices ranging from 18 to 26 shillings per pound.

The silk growing industry in Connecticut dates from 1732, and it soon made considerable progress. The first coat and stockings made of New England silk were worn by Gov. Law, in 1747; the first silk dress by his daughter, in 1750. Dr. Ezra Stiles, president of Yale College, raised silk worms and had his professor's gown made from the fruits of his industry in 1758. Orchards of mulberry trees were planted at New Haven and Mansfield, about 1760, laying the foundations of an industry in the latter town that lasted three-quarters of a century and paved the way for the present silk manufacture of that and other sections.

Nothing further of importance is recorded of the industry in the state, for the period prior to the Revolution, during which silk history in the whole country was almost a blank. In 1789 there came a revival throughout Connecticut and silk growing and home manufacture thrived until in the early years of the century it was recorded that fully three-fourths of the families in Mansfield were occupied therein. In 1810 the first out-and-out silk mill in America, erected especially for the silk manufacture, was built at Mansfield, Conn.,

by Rodney and Horatio Hanks. This was 12x12 feet in extent and is still standing.

About 1832 an important silk industry was established by Samuel Whitmarsh, at Northampton, Mass., and it was here that John Ryle, the "Father of the American Silk Industry," was first employed upon his arrival in this country in 1839. This year saw the collapse of the wonderful craze known as the Morus Multicaulis fever, which had had a phenomenal run in all sections of the country for about thirteen years. But this will be treated of later in its proper connection.

Samuel Whitmarsh, Mr. Ryle's employer, was deep into the prevailing madness. He was a manufacturer only, or mainly, to fabricate specimens of silk stuff so far as they would promote the introduction of Multicaulis Cuttings. "I shall make $25,000 by next winter" remarked Mr. Whitmarsh to Mr. Ryle in April 1839. Before the winter came the end had arrived and Mr. Whitmarsh had neither cash nor credit enough to buy a barrel of flour. When Mr. Ryle came to this country, though he had been working in his father's silk mill at Ballington, a suburb of Macclesfield, Eng., since he was a bare-footed boy of five years, going to his work at 5 a. m., summer and winter, he had never so much as seen a silk worm and he was greatly anxious to see one. A very little later there were thousands of people all over this country who wished they had never seen a member of the Bombyx family and devoutly hoped they would never see a worm or a mulburry tree again.

In the spring of 1840 John Ryle, "backed" by George W. Murray, an octegenarian New Yorker of some means, purchased a small plant of crude silk machinery, lying in disuse and covered with dust and rust on the top floor of the old "Gun Mill," at Paterson, N. J., and then and there was started the first enterprise in the way of domestic silk manufacture that was destined to live. Everything that had been done prior to this, in the prosecution of the silk manufacture proper, had been of an experimental character and ephemeral existence; some few were manufacturing braids, threads, trimmings and a few other articles in various parts of the country, but all did not amount to anything of importance. The industry planted by John Ryle still exists, after the lapse of nearly sixty years, and is being conducted by the "Pioneer Silk Company" (which is not a misnomer), at Paterson and at Allentown, this State, extensive mills being operated in both places.

Chris. Colt, who had brought the machinery from Connecticut and placed it in the "Gun Mill," where the "Colt Patent Arms Co." first carried on the manufacture of the now famous Colt repeating arms, had accomplished nothing; John Ryle made a success of the enterprise from the start and soon purchased his partner's interest and,

FIG. 25. Ribbon Weave Room. (See page 34.)

later, the Gun Mill property. As serving to show the low estate of the American silk industry in the earlier years, it is worthy of note that Mr. Ryle on one occasion went to New York to purchase raw material and could find but half a bale in the market. The other half had been sold, to go to Philadelphia, and after Mr. Ryle secured his half the market was bare.

At first, the Ryle product was sewings, handkerchiefs, "cravats," etc., but in 1846 looms were put in and weaving of dress silks was begun on a considerable scale. In 1854, Mr. Ryle built the "Murray Mill," 200x75 feet, three stories, by far the greatest silk mill ever erected in this country up to that date.

In 1855 the firm of Hamil & Booth entered the field, the second pioneer silk enterprise in Paterson, that still exists. During the succeeding years the industry in Paterson grew steadily, with now and again a period of partial stagnation intervening until there are now about one hundred and fifty establishments in the "Silk City," together with many important dyeing and finishing works and other industries adjunct to the silk manufacture proper.

In the meantime the industry has made rapid strides in other places also, Hudson County, Jersey City, Hackensack and other New Jersey towns; South Manchester, Rockville, Watertown and New London, Conn.; Northampton, Florence, Holyoke and Canton, Mass.; San Francisco, Cal., and Belding, Mich., being among the chief centers of manufacture, exclusive of the Commonwealth of Pennsylvania, whose silk history is reserved for a chapter by itself.

The total number of silk manufacturing establishments in the United States at this date is estimated by Secretary Franklin Allen, of the Silk Association of America, to be 861, located in 228 towns of 19 states. New Jersey stands first, with 257; New York next, with 228, and Pennsylvania third, with 172 establishments. Next come Connecticut with 66, Massachusetts with 59, Rhode Island with 26; none of the other states possessing any considerable number. Pennsylvania, according to Secretary Allen, has 34 broad silk plants, 19 ribbon plants, 2 thread manufacturers, 31 commission throwsters, 11 custom dye shops and 75 establishments engaged on other lines, such as tapestry and drapery silks, silk hosiery, underwear, trimmings, laces, etc.

It must be understood, however, in accepting this statement of the number of silk establishments in the United States that many of the smaller ones not infrequently eliminate silk almost entirely from their product.

Following will show the strength of the domestic industries, as indicated by the number of establishments, number of hands employed, total product, etc., at the beginning of each decade from and including 1850 to the present date:

Years.	Establishments.	Number of hands employed.	Total wages per annum.	Capital.	Value of product per annum.
1850,*	67	1,723	$297,416	$678,300	$1,809,476
1860,*	139	5,435	1,050,224	2,926,980	6,607,771
1870,*	86	6,649	1,942,286	6,231,130	12,210,662
1880,*	382	34,521	9,146,705	19,125,200	34,519,723
1890,†	524	50,913	19,680,318	51,007,537	69,154,599
1899,‡	861	93,600	36,500,000	105,000,000	125,000,000

*Wyckoff's "Silk Manufacture in the United States," 1880.
†Rose & Trumbull Co.'s "American Silk Industry," 1893.
‡Partly estimated, there having been no complete census taken since 1890.

No explanation is given by Mr. Wyckoff, the Secretary of the Silk Association of America, for the falling off in the number of establishments from 139, in 1860, to 86, in 1870, while every other item shows a steady advance of the industry. It will be observed that the growth was very marked between 1850 and 1860, that between 1870 and 1880 it was quite phenomenal and that, if the (partly estimated) figures for the beginning of 1899 are even approximately correct, the Queen Industry has grown to about double its proportions in 1890, within the past nine years.

Appended are some additional figures that will prove interesting and illustrative of the advance made in the supply of the American market with silks from domestic looms:

IMPORTS OF RAW SILK.

(From reports of the Bureau of Statistics, Treasury Department.)

Years.	Pounds.	Value.
1850,	*120,010	$401,385
1860,	*297,877	1,340,676
1870,	583,589	3,017,958
1880,	2,562,236	12,024,699
1890,	5,943,360	23,285,099
1898,	9,979,482	28,234,650

*Estimated from current prices, only the value being on record.

Last, but not least, may be mentioned the ascendancy in volume of domestic silk fabrics over imported goods, achieved by our home industry. The percentages of silk goods made in the United States,

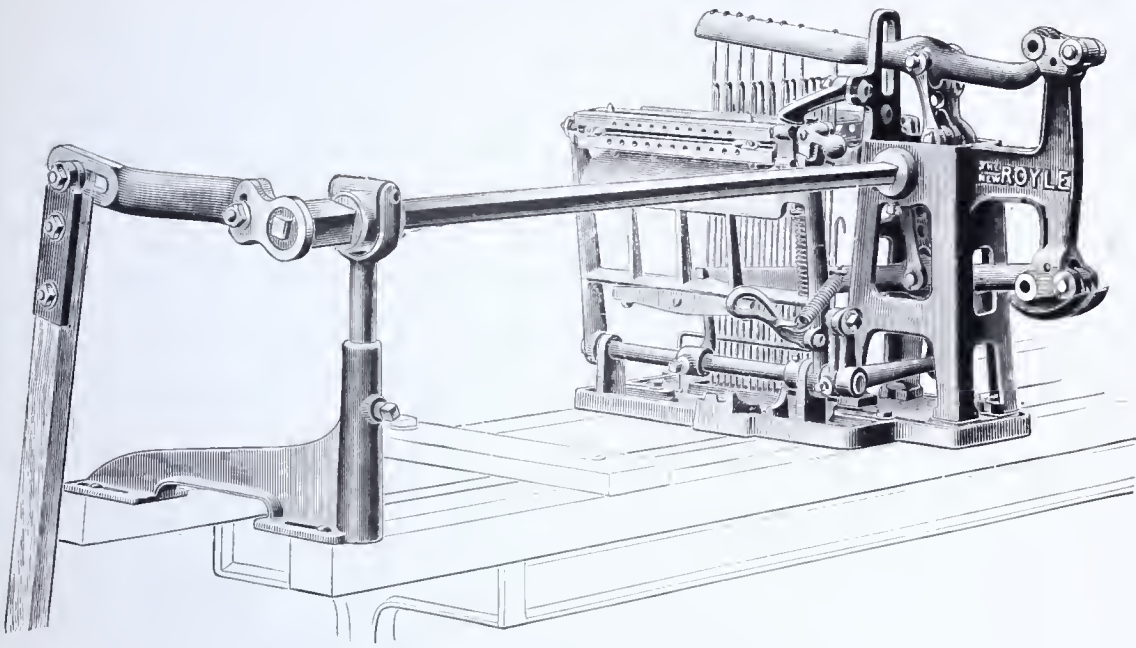

Figure 23. A Dobby. (See Page 33.)

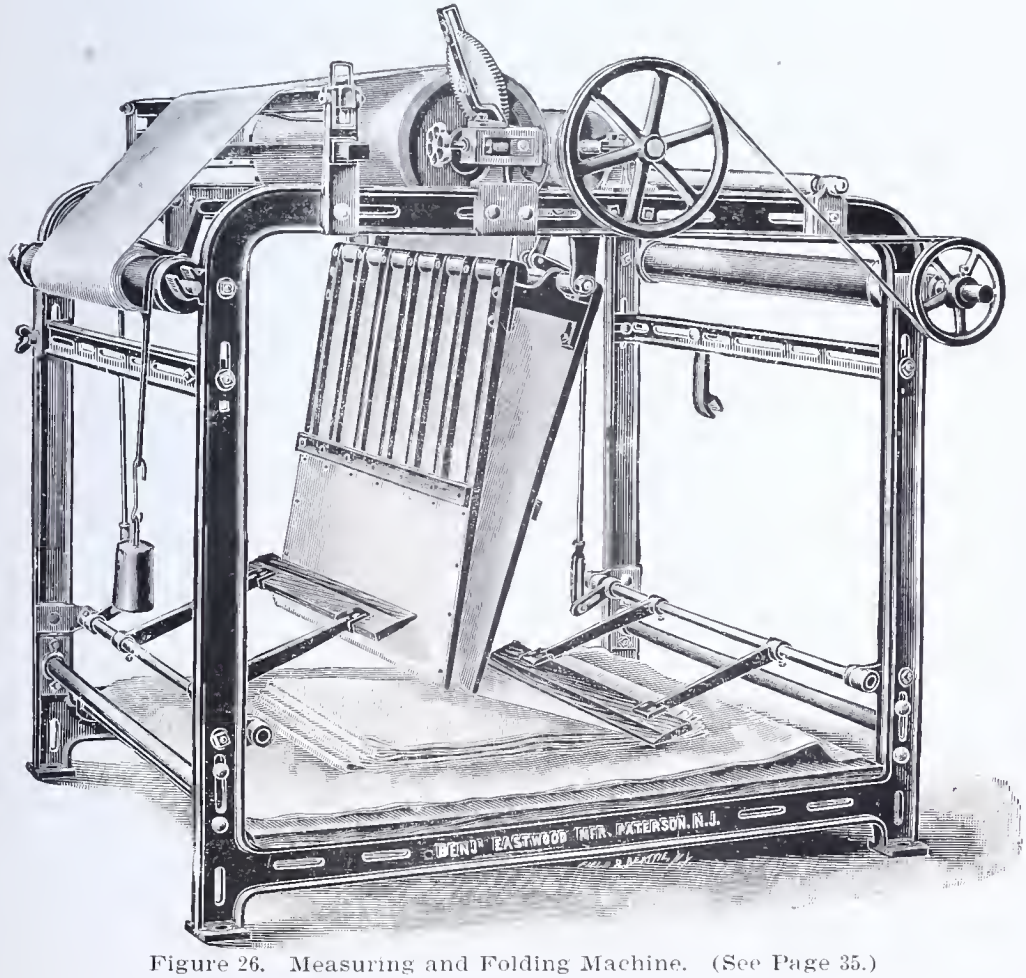

Figure 26. Measuring and Folding Machine. (See Page 35.)

as compared with the whole consumption of such goods in the country for the past (nearly) four decades, are as follows:

1860, ...	13 per cent.
1870, ...	23 per cent.
1880, ...	38 per cent.
1890, ...	55 per cent.
1898, ...	80 to 85 per cent.

It will be seen from above that within thirty-eight years this country has increased its volume of silk production until the "tables have been turned," so to write, for in lieu of importing all but 13 per cent. of the silk goods consumed by our people, it is now producing all but about 13 per cent. of the total home consumption, the imports at present consisting mainly of the extremely rich and costly fabrics from the hand looms of Lyons, Crufeld and Zurich.

About the only thing we have to fear is the Orient, where Japan and China, since the "open door" policy is extending, are rapidly adopting the use of the most modern machinery, appliances and methods, which, added to the cheap labor of those countries, may make them dangerous rivals in the near future.

It is interesting to note the advance in the home silk industry, as illustrated by our consumption of raw material from Japan, our chief source of sepply, and we may remark, in this connection, that our takings from Italy, China and other silk-producing countries has been in nearly or quite the same ratio.

But we will take the Japanese export as the strongest illustration of our growth. The total export of silk from Japan in the two decades, 1878 to 1898, which amounted to 718,266 bales, we find that Europe took 361,116 bales and America 357,150 bales, a difference, for the whole period, of but 3,966 bales in favor of Europe. But this preponderance was all gained in the earlier years of the period. In 1889-90, America forged ahead of all Europe in her consumption of Japanese raw and widened the distance steadily until the recorded imports of last year (1898) show that our consumption of the "noble fibre" from Japan nearly doubled that of Europe, the exact figures being: America, 37,019 bales; Europe, 19,734 bales. These figures were recently given in the Tokohoma Gazette, and should be thoroughly reliable. They, taken together with other data, prove that *America is to-day the greatest silk manufacturing country in the world*, judged by its volume of production.

In addition to the preceding details, the dates of starting the silk manufacture in various localities may be briefly stated as follows:

1815. Philadelphia, Pa., trimmings, etc.

1829. Baltimore, Md., ribbons.

1834. Boston, Mass., dress trimmings.

1834-1838. Florence, Mass., sewing silk.
1835. Dedham, Mass., sewing silk.
1838. South Manchester, Conn., general silk manufacture.
1838. Windsor Lock, Conn., sewing silk.
1840. Paterson, N. J., general silk manufacture.
1840. Canton, Mass., sewing silk.
1842. Newark, N. J., sewing silk.
1843. Philadelphia, Pa., sewing silk.
1848. Skinnerville, afterward moved to Holyoke, Mass., sewing silk.
1849. Watertown, Conn., sewing silk.
1852. Philadelphia, Pa., ribbons.
1863. Rockville, Conn., sewing silk.
1865. Trenton, N. J., coach lace.
1865. New York, N. Y., general silk manufacture.
1866. Willimantic, Conn., sewing silk.
1866. Oneida, N. Y., sewing silk.
1868. Hoboken, N. J., silk dress goods.
1870. San Francisco, Cal., sewing silk and fringe silk.
1871. Brooklyn, N. Y., silk laces.
1872. College Point, N. Y., ribbons.
1874. Wortendyke, N. J., silk handkerchiefs and dress goods.
1875. Town of Union, N. J., silk dress goods.
1881. Allentown, Pa., broad silks.

THE SILK INDUSTRY IN PENNSYLVANIA.

Pennsylvania, now ranking third in order among the silk manufacturing states—judged by the number of establishments engaged in the industry—and which is so rapidly forging ahead that it is safe to predict that it will soon lead them all, is found to have been engaged in seri-culture at a very early date in her history, having been preceded in it only by Virginia, the Carolinas and Louisiana, all the other silk growing colonies following, most of them many years later.

It was recommended by James Logan to the Penn family, in 1725, as "extremely beneficial and promising;" the next year he mentioned that silk from the colony had been sent to England; he "is glad it proves so good."* A bill had been introduced in 1719 into Parliament to restrain the increase of woolen and other manufactures in

*"Annals of Philadelphia" by John F. Watson, Philadelphia, 1830.

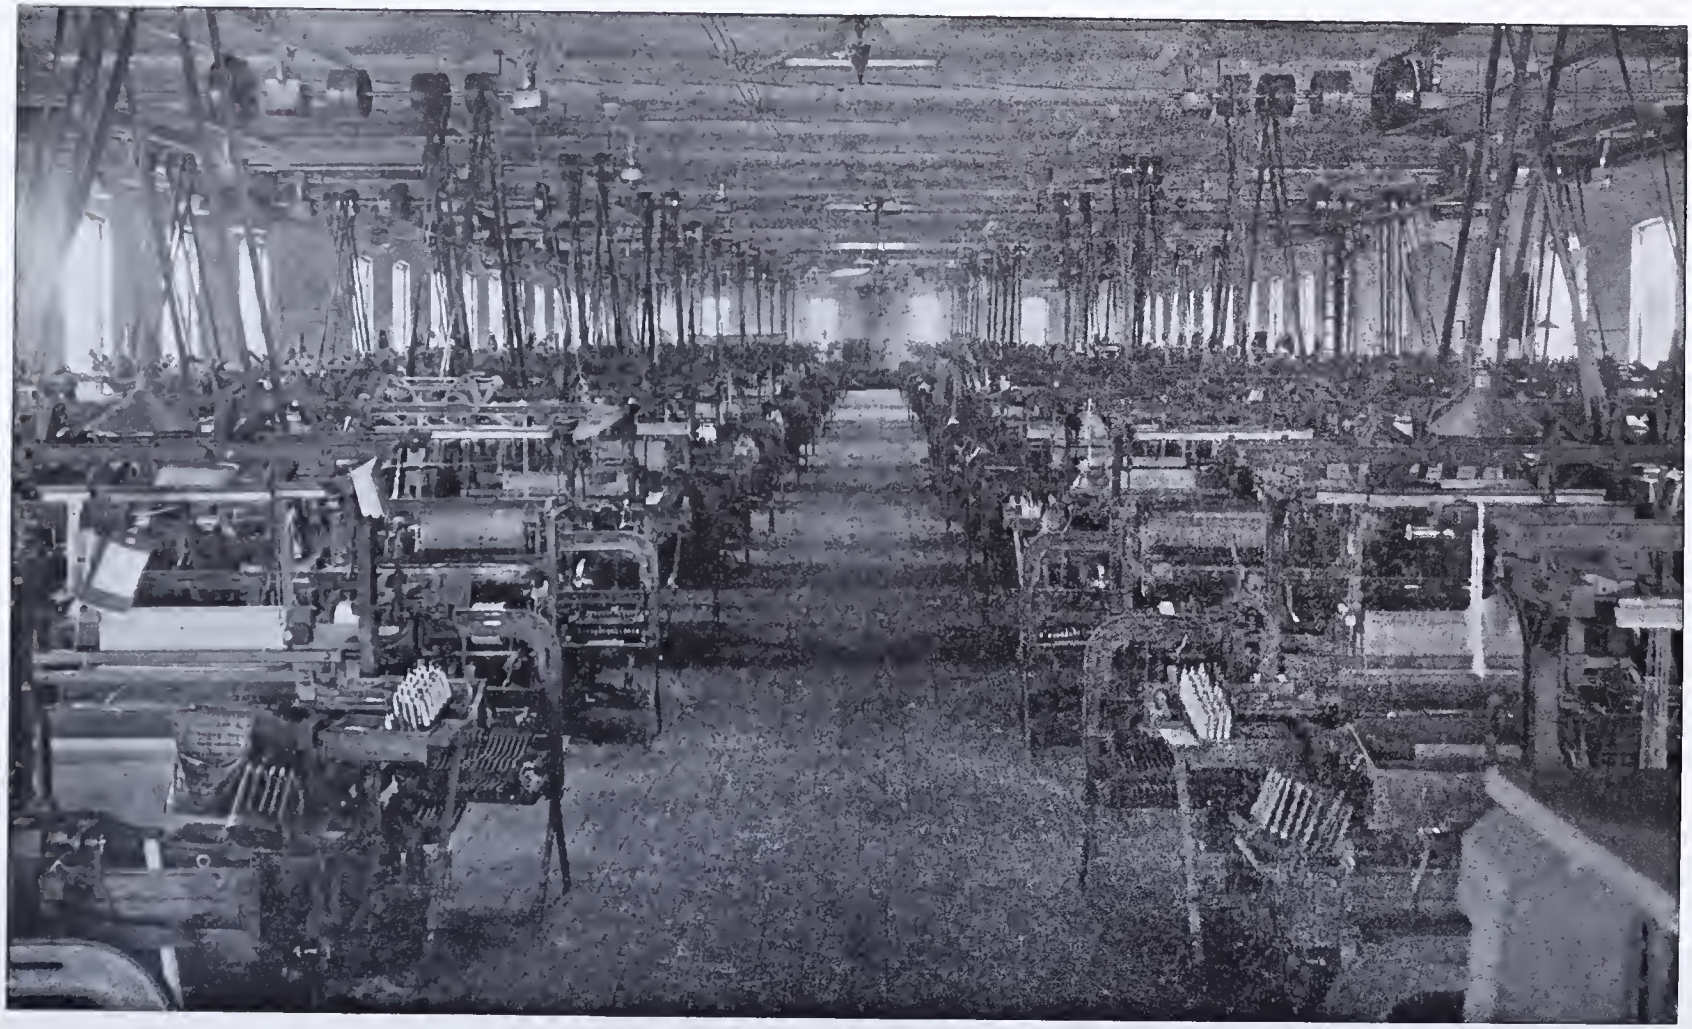

FIG. 27. A Modern Weave Shop, Broad Silk Looms. (See page 35.)

the colonies.† A more definite application of the non sibi sed aliis principle was urged a few years later, based on a complaint that the colonists were engaged in textile manufacturing, especially in the provinces north of Virginia. The British Board of Commissioners on Trade and Plantations made an elaborate report on this subject to Parliament in 1732. They say:

"It were to be wished that some Expedient might be fallen upon to divert their thoughts from Undertakings of this Nature; So much the rather, because those Manufactures in Process of Time may be carried on in a greater Degree, unless an early Stop be put to their Progress, by employing them in Naval Stores."

The conclusion arrived at is as follows:

"We would humbly beg Leave to report and submit to the Wisdom of this honourable House, the Substance of what we formerly proposed in our Report on the Silk, Linen and Woolen Manufactures hereinbefore recited, namely, whether it might not be deemed expedient to give those Colonies proper Encouragements for turning their Industry to such Manufactures and Products as might be of Service to Great Britain, and more particularly to the Production of all kinds of Naval Stores."

Ultimately, it seems to have been considered that the encouragement of silk culture was one of the "expedients" for preventing manufacture. The commissioners addressed a letter, in 1734, to the deputy governor of Pennsylvania, Patrick Gordon, asking him what encouragement should be given in order to "engage the colonists to apply their industry to the cultivation of naval stores of all kinds, and, likewise, of such other products as may be proper for the soil of the said colonies, and do not interfere with the trade or produce of Great Britain." To this Governor Gordon replies that it was the whole study of the merchants how to make returns for the large importations of British manufactures. He recommends, among other things, that the culture of silk be encouraged, and mentions that small quantities had already been produced in the colony, equal to the best European.

A London paper of February 7, 1765, states that within four days one hundred journeymen silk throwsters had engaged passage to New York and Pennsylvania, under extraordinary encouragements, intending at both places to establish the manufacture of silk. Perhaps the "encouragements" arose partly out of reports concerning efforts which were begun about this time by Dr. Benjamin Franklin.

Several hundred pounds sterling were paid to Pennsylvania and other American colonists between 1755 and 1772, for premiums on silk and mulberry trees, by the London Society for the Encouragement of Arts, Manufactures and Commerce. A pamphlet published by the society mentions that in 1761 the following corresponding

†Anderson's "Origin of Commerce."

members were authorized to pay premiums in their respective colonies: Dr. Jared Eliot, the Rev. T. Clap (president of Yale College), and Jared Ingersoll, of Connecticut; Benjamin Franklin, LL. D., and John Hughes, of Pennsylvania; George Pollock, Cullen Pollock and John Rutherford, of North Carolina; M. Ortolengi (superintendent of the filature at Savannah), of Georgia.

The bounties paid in other colonies by the society were probably the same as those announced at that date for Georgia, viz, for first quality cocoons, 3 d. per pound; for second quality, 2 d., and for third quality, 1 d. per pound.

About the year 1766, Dr. Nathaniel Aspinwall, of Mansfield, Conn., who had a nursery of white mulberry trees on Long Island, and who was a person of large public spirit and enthusiasm in respect to silk culture, gave a number of such trees to be planted near Philadelphia. An act giving bounty for planting the tree had been recently passed by the legislature of New Jersey, and considerable interest was manifested in the subject by other neighboring colonies.

The American Philosophical Society of Philadelphia, of which Dr. Franklin was a leading member, gave much consideration to plans for silk culture in 1768 and 1769. Early in 1770, Dr. Franklin, who was then in London, wrote a letter to the society, urging these projects and enclosing his correspondence with Dr. Cadwallader Evans, of Philadelphia, upon the subject. This seems to have determined the society's course; they took prompt steps for establishing a filature. A subscription for the purpose was started, and, during the first year the sum of £875 14 s. was obtained.

Measures were taken to procure supplies of mulberry trees and silk worm eggs, and Dr. Franklin, who was always ready to contribute good advice, sent a copy of a useful work by Abbé Sauvage. An application was made to the assembly to authorize "a public filature," the managers to have power to grant premiums equal to about £500 per annum for five years.

The filature was actually opened in June, 1770. It was situated in Seventh street, between Arch and High streets. About 2,300 pounds of cocoons were brought thither in 1771; of this amount, 1,754 pounds were bought by the managers; two-thirds of the cocoons had been raised in New Jersey. There is room for doubt as to the disposal of the products. It is more than hinted that all the silk made was absorbed in garments for members of the society. J. d'Homergue, who was a competent witness, though perhaps not wholly disinterested, says:

"I have not heard of any raw silk having been prepared at this filature, or sold out of it, yet I have been told that a lady of this city (Philadelphia) had a negligee dress manufactured in England out of silk of her own raising."

A considerable number of successful attempts at silk culture were made at this time in Pennsylvania, several of which have passed into history. Susannah Wright, of Columbia, Lancaster county, a Quaker lady of some literary celebrity, reeled and wove from home grown cocoons a piece of "mantua" sixty yards in length. A dress was made from this fabric for Queen Charlotte, and for a second time the wife of a British sovereign honored the colonies by appearing at court in American silk.

It is further recorded that Susannah Wright had 1,500 worms in 1772, "and could have raised large quantities if encouraged;" she also made sewing silk. Another Quaker lady, Grace Fisher, who was a noted preacher, made some silk fabrics which were presented by Governor Dickinson to Mrs. Catharine Macauley, the historian. There are several instances about this time of Pennsylvania ladies raising the material for their own clothing, and at least one of a bride thus providing her own wedding garment; but, it is significantly added, "the best dresses worn with us were woven in England."

The following letter from George Washington shows how active in the work were the women of the last century:

"Philadelphia, July 29, 1794.

"Madame: Not before the 8th inst. had I the honor to receive your favor of the 17th of May, accompanied with a piece of silk of your manufacture. Contrary as it is to an established maxim of mine not to accept a present from anyone, yet, considering this as a mark of your peculiar attention to me, and as an evidence of what our climate, aided by industry, is capable of yielding, I receive and thank you for this evidence of your skill. I shall have it made up, and will wear it as a memento of your politeness, having the honor to be,

"Your most humble and obliged honorable servant,

"GEORGE WASHINGTON."

Many writers have lamented the complete interruption which the Revolutionary War caused to the silk enterprises. In fact, however, the war made the real industry practicable. Silk culture here, to supply manufacturers abroad was precisely the reverse of a profitable arrangement for this country. "If, when we plough, sow, reap, gather and thresh we find that we plough, sow, reap, gather and thresh for others, why should we repeat the unprofitable toil?" Legislation to stop manufacturing in America was now the order of the day in England. An act of Parliament, 3 Geo. II, c. 29, sec. 9, passed in 1750, provided that:

"From and after the 24th day of June, 1750, no Mill or other Engine for slitting or rolling of bar Iron, or any plaiting Forge to work with a Tilt-hammer, or any furnace for making of Steel shall be erected or, after erection, continued in any of his Majesty's colonies in America."

Act 14 Geo. III, c. 71, was passed in 1774, "To prevent the exportation to foreign parts of utensils made use of in cotton, linen, woolen and silk manufactures of this kingdom." The statute imposed a fine of £200 for transgression; such machinery could be seized and confiscated, its holder anywhere was liable to arrest, and even the ship that carried it and the owners of the vessels were reached by the stringent penalties of that law.

The United Society for Promoting American Manufactures (Philadelphia) recommended, in 1776, an appropriation of £40 for the encouragement of John Marshall, who had constructed some novel machinery for throwing and twisting silk. The invention was at once too early and too late. The arts of peace were suspended, and the people were preparing for war.

Silk history in this country is almost a blank during the struggle for independence, and for several years afterwards its records are very faint.

The great demand and high price of breadstuffs, owing to the wars growing out of the French revolution, rendered the cultivation of grain so profitable for many years that the mulberry was neglected.

Subsequent revivals of interest in culture and manufacture seemed unimportant at the outset. But small as were these beginnings, they proved more permanent (because they obtained a home market) than all the carefully nursed silk culture for export which had been attempted since the country was settled. The manufacture of sewing silk gave new life to an industry that had sickened and died when fed on royal favor and parliamentary bounty.

It may here be mentioned, however, that at the period of the Revolution and for at least fifty years afterward, the making of sewing silk in this country was chiefly a household art rather than an organized business carried on in a mill or factory. This was the bridge between the silk culture of the colonies and the full-fledged manufacture of the present century; a bridge of essential service, though a chasm yawned at its farther end where many fortunes were engulfed.

The methods of reeling from the cocoon and of making sewing silk were of the most primitive kind. The reeled silk was called "tow," and it looked like that material, being coarse, of irregular thickness of fibre and almost wholly wanting in lustre. By a laborious hand process this was converted into sewing silk of fair quality, but only half the amount in weight could thus be successfully manipulated; the rest was a knotted, irregular refuse, barely available in making homespun garments.

The sewing silk, or "twist," had a low reputation as compared with that imported from Italy. It was put up in small parcels, called "sticks," containing a definite number of yards. Twenty-five skeins

were tied in a bunch, and four bunches were fastened together; this gave a merchantable package of 100 skeins—a unit of trade that was used in barter and took the place of currency. Very little money was used at that time in the State, and the sewing silk became the "circulating medium." An act of legislature defined the length of the skein, and was enforced by penalty, as follows:

Any person or persons who shall offer for sale any sewing silk, unless each skein consists of twenty threads, each thread of the length of two yards, shall forfeit the sum of seven dollars to any person who shall prosecute the same to effect.

Naturally enough, when the medium of trade had thus acquired an artificial value, it became the interest of each producer of this currency to debase it. This was effected in two ways: by making the thread as fine as possible, so as to get the greatest length out of a given weight of material, and by putting only half the length in a skein and calling it a "half skein."

The object of the latter device was to give an opportunity, as the silk went from hand to hand, of passing half skeins as whole ones. The chance of this immoral advantage made the half skeins the more popular currency.

An improvement in the spinning wheel was patented in the year 1800 by Horace Hanks; it was known as the "double wheel head." This gave the spindle an increased speed of 145 turns to one as compared with the old-fashioned machinery.

The making of fringes, coach laces and tassels at Philadelphia began in the year 1793. It was expanded in 1815 to include silk trimmings, naval sashes, ribbons, braids, etc., of various kinds, by Wm. H. Horstman, who came to this country from Cassel, Germany, in that year and settled in Philadelphia, where his decendents still continue the business then founded. Mr. Horstmann had learned the art in France and was the inventor of much silk machinery. He was the first to introduce the Jacquard attachment, in 1824. In 1837 his son, William J., designed and built power looms and introduced their use in weaving ribbons and other narrow goods.

There is a record of fresh exertions by Mr. Aspinwall, in 1790, to extend the planting of the mulberry in Pennsylvania, New York and New Jersey, but the insuperable difficulty during all this period arose from the bad reeling of domestic silk. No power-driven machinery that has ever been devised is capable of making a good, uniform thread from such reeled silk as was then produced in the households of the silk growers, although, as has been stated, a fair sewing silk could be extracted from it by hand work, with great loss of raw material. The bad reeling which was customary seems more remarkable since several excellent kinds of hand reels, with a traverse, had been constructed by inventors of that day. Success at last

attended the efforts put forth and with good reeling "the native silk was found to be of superior quality and strength, winding and doubling with greater facility and less waste than China or Broussa silk." The comparative cost is not stated.

In December, 1825, the subject of silk culture began to receive national attention, being brought before Congress by a resolution of inquiry introduced by Mr. Miner, of Pennsylvania, and referred to the Committee on Agriculture. During the following spring the committee reported favorably, presenting, among other arguments on the subject, a statement that "the value of silk goods imported in 1825 was nearly twice as great as the export of breadstuffs." The report included a resolution directing the Secretary of the Treasury to cause to be prepared a well-digested manual on the growth and manufacture of silk.

Inquiries for information upon the subject were sent out by the secretary, Richard Rush, in 1826, and from the replies and other material, a manual was constructed, entitled "Letter from the Secretary of the Treasury," dated February 7, 1828. Six thousand copies were printed by order of Congress. This manual became known as the "Rush Letter;" it contains 220 pages, besides illustrations of machinery, and is a carefully executed work. Other documents relating to silk culture were received and published by Congress at this time.

A report presented to the House in 1830 by the Committee on Agriculture, included two interesting letters from Peter S. Du Ponceau, LL. D., who accompanied Baron Steuben to this country in 1777, and afterward rose to eminence at Philadelphia in public affairs and in studies of philology and law. Essays on American silk by John d'Homergue also formed part of the report. The essays and letters contain much useful information, largely drawn from the experience of their authors in raising silk. The report proposed a grant to M. d'Homergue of $40,000 for the establishment of a Normal School of Filature at Philadelphia, to supply gratuitous instruction to sixty young men for two years in the details of reeling, dyeing and manufacturing silk.

M. d'Homergue was to be authorized meantime to travel through the different states and teach the art to farmers and others. A bill containing these propositions was brought to a vote in 1832 and was defeated by a small majority. The subject was again referred to the Committee on Agriculture, which, in 1835, made an adverse report, on constitutional grounds.

In the following year the matter was referred to the Committee on Manufactures, which reported in 1837. This last report, which was very elaborate, declared that the "silk bill" was defeated because the "ingenuity and experience of our countrymen now render it un

necessary, believing, as they do, that the recent improvements in reeling will do more in a few weeks than the establishment of many normal schools on the old plan will do in many years." The committee recommend that all public lands in the United States be leased gratuitously wherever the cultivation of the mulberry and the sugar beet were undertaken thereon.

During the pendency of the bill in 1830, Mr. Du Ponceau started a small filature of ten reels and twenty operatives on his own account, under M. d'Homergue's direction, at Philadelphia. Among the first fruits of his labor were two flags of American silk; these were presented respectively to the legislature of Pennsylvania and to the United States House of Representatives. About sixty pounds of the silk prepared at this filature was submitted to different manufacturers, who reported upon it as of excellent quality.

The subject of silk culture gained the public ear, and the legislatures of several states passed bills for the encouragement of the new industry. The tendency during the years immediately preceding 1837 was towards venturous enterprises, and silk culture presented an attractive field. A peculiar variety of the mulberry tree, believed to possess many advantages as compared with the white mulberry (Morus alba) was brought to public notice, and a speculation was started of such rapid and extensive growth that in a few years it overshadowed all other silk enterprises and changed the whole course of the industry.

Gideon B. Smith, of Baltimore, claimed to have owned the first Morus multicaulis tree in the United States it was planted in 1826. Dr. Felix Pascalis, of New York (afterwards editor of a publication called The Silk Culturist), called attention to the supposed merits of this plant in The American Journal of Science, July, 1830, and described its introduction into Europe by Samuel Perrottet, of the Linnaean Society of Paris. Dr. Pascalis predicted that by its culture two crops of silk could be raised in a season; the prediction was soon afterward apparently verified.

The tree was said to grow with marvelous rapidity, developing large, thin, tender and succulent leaves, in profusion. It could be propagated easily by cuttings; it could be cultivated as a shrub; its leaves formed the choicest and most nutritious food for silk worms, etc. All the agricultural literature in the country soon became suffused with descriptions of this wonderful tree. In 1831 the Massachusetts Legislature ordered the preparation of a manual on silk culture. The work was performed by Jonathan H. Cobb and the manual passed through at least four editions, and spread the new gospel of Morus multicaulis throughout all the states.

This was the beginning of a veritable madness, a craze that carried people of all classes off their feet. Nothing approaching it was ever

known in any country save only in Holland, where the "tulipomania" had rose to its full development some two hundred years before. Not only agriculturists, but grave doctors of divinity, law and medicine, scholars, tradesmen and mechanics, men and women, old and young, were infected with an insane passion to raise mulberry trees. The future of these people was a glorious mirage, a radiant and irridescent phantasmagoria, every vision of which was to be abundantly realized. Everybody was to become suddenly rich; every woman in the land was to possess a dozen silk dresses at the very least. Dr. Pascalis was most jealous in promulgating the wonderful gospel, and opened the "Pandoras box" to countless victims.

The list of stock companies formed for raising and manufacturing silk at this time is very long; their lives were very short. Many of them were slenderly equipped in both knowledge and resources. Six were formed in Pennsylvania and nearly as many in neighboring states and a few in the west. A United States Silk Society was organized at the national convention, held in Baltimore, in 1838. The number of private individuals engaged in silk raising cannot be estimated. In some sections, says a writer of the day, "you can scarcely go into a house but you find the inmates engaged in feeding worms."

The literature of the period on this subject was abundant and various. In the following list, the titles of some of the more noted publications are presented:

Authors—James Mease, M. D., of Philadelphia, "Letter to Secretary Rush;" U. S. Twentieth Congress, House Doc. 158; John Clarke, "Treatise on the Mulberry and Silk Worm," Philadelphia; Peter S. Du Ponceau and John d'Homergue, Philadelphia; Gideon B. Smith (Ed. American Farmer), Manual, Baltimore; also Ed. "Journal of the American Silk Society and Rural Economist," 2 vols., Baltimore, 1840; "American Silk Grower and Farmers' Manual," Philadelphia; Dr. Felix Pascalis, "Instructions for Silk Worm Nurseries, and Culture of the Mulberry Tree."

This literature is, in one respect, peculiar. Its errors lie all in a single direction. The silk production in past years is often overstated; the probable yield from trees, eggs and cocoons is often overestimated; plentiful profits are calculated, but the mistake of understating is nowhere made.

Gradually, but at an increased rate of velocity, the tide of speculation rose. Large as were the anticipated profits of producing silk, they were insignificant as compared with the fortunes to be made by raising the new mulberry tree. Orchards of it were planted in every state in the Union. The demand raised the value abroad, so that trees which had been worth 8 to 12½ cents each in France could not be bought there on a remittance of less than 18 to 30 cents.

In December, 1838, sales were made in this country at $1.00 per

tree, but the owners withdrew most of the lot, being dissatisfied with the prices obtained. Trees of a single season's growth were sometimes sold at $5.00 each. A belief in the profit of silk culture was, of course, the basis of the demand for the tree, and a table was published showing that in the actual experience of fourteen people an average of $1,000 per acre had been obtained, at $4.00 per pound of silk. But the value of the trees became greater than that of the silk which they could, by any possibility, be the means of producing.

One farmer who planted $1,000 worth of Morus multicaulis in 1838 on three-quarters of an acre, sold the trees next year for $6,000. The sales in a single week in Pennsylvania exceeded $300,000, and in many cases the same trees were sold two or three times at advancing prices. In other instances the proceeds of fifteen acres were $32,500; of two acres, $4,000; of ten acres, $38,000. The exact procedure at one of these sales is given as follows:

"Annexed is a correct statement of the number, prices and proceeds of the Morus multicaulis, sold September 18, 1839, at auction, at the Highfield Cocoonery, Germantown, Pennsylvania. The trees were sold as they stood in the ground; those under twelve inches to be rejected. Owing to a thin soil and close planting, the sizes of the trees were generally small and the branches few; the average height, according to an estimate made on the ground, being about two and one-half feet. The purchasers were mostly from a distance, the largest portion being from Illinois, Missouri and other western states. Two hundred and sixty thousand trees were sold at prices ranging from 17 to 37½ cents per tree, averaging 31 23-100 cents per tree, or 12½ cents per foot in length of stalk. The total sale was $81,218.75."

The discovery was made that cuttings with eyes or buds were sufficient for planting an orchard; the "American Silk Grower" announced:

"On Friday last, the steamboat Alabama took up to Baltimore 22,000 mulberry switches (Morus multicaulis) from six to eight feet in length; the value of which, at the lowest calculation, based upon actual sales all through the country, cannot be less than $45,000. The number of eyes or buds on these 22,000 switches is ascertained by carefully counting them, to be 2,254,000, which, according to prevailing prices, would be considered cheap at 2 to 2½ cents apiece. The whole were raised on fifteen acres of such land as would be considered well sold at $10 an acre in ordinary situations."

The bubble burst in 1839, after a continuance of thirteen years. Silk culturists, manufacturers and others had everywhere been swept into the rising current. As for the tree speculators, it is related that one, who had been among the most successful, sent an agent to France with $80,000 to buy trees and cuttings in the winter of 1838-9, with result as follows:

"Before the whole of his purchase had arrived the crisis had come. The nurserymen had failed for so large a sum that he could never reckon up his indebtedness, and the next spring his multicaulis trees were offered in vain to the neighboring farmer at $1.00 a hundred for pea brush."

People were angry and vociferous over their losses and pulled up most of their mulberry orchards in a rage. In every village, numerous gardens and outlots might be seen planted with multicaulis; later, these trees had become a worthless incumbrance, and in many instances were rooted out and thrown away.

For a few years after the collapse of the multicaulis some interest was taken in the hardier Morus alba, or white mulberry. Two trees of one season's growth raised by Elder Sharpe, of North Windham, Conn., were sold standing in his nursery in August, 1842, at auction, for $106 and $100. Further sales were withheld because the bidding was not considered sufficiently spirited. In 1844, a blight of a general character, to which even the hardy white mulberry yielded, gave the finishing blow, and silk culture in America practically ceased to exist.

The exceptions have included the spasmodic attempts at seri-culture made in intervening years at San Diego, Cal., in various parts of Kansas, in several of the southern states and, most notable of all, by the Woman's Silk Culture Association of the United States, at Philadelphia, the utter collapse of which enterprise, after nineteen years of noble effort, has recently been announced. The work of the association deserves something more than a mere passing notice.

The Women's Association began its work in 1880, at Philadelphia, with the hope of being able to provide for the women of the country an interesting and instructive as well as a remunerative source of employment, easily made accessible to the thousands of small householders and needy people of the country districts, who are cut off from the labor channels of cities and the liberal patronage of the rich. To these people, it was believed, the cottage culture of silk as an auxiliary to their slender incomes would answer a long-felt want.

At the start the association received almost a boom; the first meeting was largely attended and the board of officers included many women prominent in philanthropic work; Mrs. John Lucas was the president. The first efforts of the Association were to open schools of instruction, one at No. 1328 Chestnut street, and another in the building of the Permanent Exhibition Company, at the Centennial grounds. Two classes only were formed for the first crop. Trees and cuttings in large quantities and many ounces of eggs were distributed in nearly a score of states.

With the second year came the first fruits of the Association, and cocoons were received from these states, and upon reeling these

Figure 28. Mrs. Garfield Dress Pattern. (See Page 63.)

cocoons it was proved that American-raised silk was equal if not superior to the best classic silk of Italy. It was during this year that silk was collected from fourteen states and was woven into a dress pattern and presented to Mrs. Lucretia Garfield, widow of President James A. Garfield. Thus it was proved that nearly every part of the United States is adapted to silk culture. See Figure 28.

The first real trouble of the Association came with the third year of its existence. Owing to the removal of the Permanent Exhibition Building in the park, the main school of instruction was transferred to the building used by the German Government during the Centennial Exposition. Heavy expenses were incurred in fitting up the property, and to this was added one night a very material loss. A robbery of a large number of silk worm eggs and worms in the process of feeding almost depopulated the cocoonery.

The California Legislature appropriated $7,500 for fostering silk culture in that state, and the Association petitioned the Legislature of Pennsylvania for $5,000 per annum for five years to carry on the work in this State, but the request was denied.

At the spring session of Congress of 1884, the National Government was appealed to for aid, and during the following year flags of American silk were presented to the Senate and House of Representatives of the United States and both branches of the State Legislatures of Florida and Pennsylvania.

The following year brought the first aid from the Government, the establishing of an experimental station in Philadelphia and the appointment of Mrs. John Lucas, president of the Women's Silk Culture Association, as its superintendent. This gave Mrs. Lucas the direction of the expenditure of $2,500 per annum and a salary of $1,200. The latter she donated to the Women's Association, and greatly relieved the depleted condition of its treasury.

It was not, however, until the early part of 1886, when the National Government came to the rescue with an appropriation of $5,000, that the Association was on a firm financial basis. The work of the Association progressed more encouragingly as a result of the new incentive, and for the first time the women were able to show a premium silk culture.

Sericultural instruction progressed during 1887, and in September of that year an exceedingly creditable display had been prepared for the industrial parade of the Constitutional Centennial Celebration, in Philadelphia. Much had been expected from this exhibit, in the way of making public the work of the Association, but fate again dealt a crushing blow at a time of prosperity. While the float was waiting on Norris street for its turn to fall in the line of procession, some unknown person either carelessly or maliciously threw a lighted match upon the plush canopy, which took fire and burned rapidly.

While several persons were extinguishing the fire, vandals and thieves looted the float, carrying away several hundred dollars' worth of plush, silk, reeled silk and cocoons, and the opportunity of proving their work was again denied the women.

The scarcity of mulberry trees—the food of the silk worm—occasioned no little difficulty to the silk culturists, and Congress was constantly appealed to for these trees. The planting of mulberry and Osage orange trees was urged by the Women's Association, and in one year, 1888, it distributed nearly 10,000 trees throughout the silk-producing districts.

Congress failed to pass an annual appropriation of $5,000 in 1890 and the downfall of American silk culture began at this time. The withdrawing of financial support at a time when success was almost in view completely shattered the enthusiasm of the workers and dealt a blow to the industry from which it never recovered.

Meanwhile, step by step, improvements had been effected in the manufacture of silk goods. As early as 1828, Toerhoven Bros., of Philadelphia, had invented a machine for reeling, doubling and twisting at once. Similar inventions by others had a similar object—to reel silk and to make sewing thread by one operation. But success did not lie in this direction. Improvements in the machinery for winding, doubling and spinning were introduced about 1838 and proved of permanent value. One of the most important of these is the "friction roller." This device avoids the unequal twist in the thread, which otherwise arises from the increase of diameter as the wound silk accumulates upon a bobbin.

It is interesting to the people of this Commonwealth to note the large share that Pennsylvania has had in the steady growth of the domestic silk industry. As already shown, this State now stands third in importance, judged by the number of its silk manufacturing establishments; but there are other ways in which to illustrate the advancement made within the years that have elapsed since 1860, at which date the first fairly reliable statistical data was collected and formulated.

It should be understood, however, that the figures that follow, which are for the five chief silk manufacturing states, are not the result of the work of this Bureau, but are taken from the various United States census reports, which were formulated in each census year by different statisticians, pursuing each his own method, leading, in some instances, to apparently conflicting results. They are at least approximately correct, and, while they are not of equal value to the carefully prepared and thoroughly accurate statistics of this Bureau, will yet serve the purpose for which they are presented; in fact, there is no other data in existence covering the greater part of the period in question:

SILK MANUFACTURE IN FIVE STATES—1860.

States.	Number of establishments.	Number of hands employed.	Total wages paid.	Number of broad and narrow goods looms, both hand and power.	Capital employed.	Value of material consumed.	Net value of product.
New Jersey, ...	9	716	$111,492	.....	$207,600	$631,725	$569,700

SILK MANUFACTURE IN FIVE STATES—1890.

States.	Number of establishments.	Number of hands employed.	Total wages paid.	Number of broad and narrow goods looms, both hand and power.	Capital employed.	Value of material consumed.	Net value of product.
New Jersey, ...	132	17,517	$7,176,180	11,714	$19,035,241	$17,875,430	$30,760,371
New York, ...	185	13,151	5,584,399	4,940	16,668,455	10,141,079	19,417,796
Pennsylvania, ...	66	9,522	2,981,334	3,589	10,844,294	12,084,900	*19,357,546
Connecticut, ...	35	5,081	2,006,804	1,378	9,265,883	6,198,476	9,788,951
Massachusetts, ...	20	3,216	1,296,399	540	3,659,838	3,251,023	5,557,569

*This is the gross value, but in the Census Report for 1890, we find: "The gross production of Pennsylvania, amounting to $19,357,546, is much nearer the total value of its silk manufactures than the sum of $11,404,223, the value of its completed goods, because a large portion of the thrown silk produced in that State is not made into goods there, but goes elsewhere for manufacture."

As good a statistician as William C. Wyckoff, secretary of the Silk Association of America, for several years, including 1880, in his report for that year (in which he also presents the statistics for 1860 and 1870) places Pennsylvania second to New York only in the number of its establishments, and first in the number of hands employed, in the amount paid in wages, in capital employed, in the value of material consumed and in the value of its product.

This will be seen by a glance at the foregoing figures for that year; also, it will be seen that the statistics for 1870 and 1880, by the same author, as well as those of 1890 by Special Census Agent Byron Rose, do not confirm the showing for 1860, which is manifestly an error. The Eleventh Census report (1890), however, shows that at the date of its publication the silk industry of this State had attained third place in the number of establishments and in all other respects save only in that value of material manipulated (in the throwing branch mainly), in which it stood second, while in value of product New York held second place with a difference of but $60,250.

The Twelfth Census will doubtless show an enormous gain of the silk industry in Pennsylvania over all other silk states, the growth within the past few years having been something quite phenomenal, and it is gratifying to note that there are no signs of its abatement. Of the new mills that have been established of late, many more have come to Pennsylvania than to all the other states combined, the attractions being liberal treatment in the matter of taxation and financial aid in building, an ample supply of intelligent labor, from a sober, thrifty, industrious class that are unequalled anywhere; also,

freedom from constant labor agitation, strike influences, the advantage of cheap fuel and many other things that, taken together, are making the Keystone State a veritable industrial "Mecca," toward which all eyes are turning and all steps are tending of those whose aim is to prosecute the business of silk fabrication under the most favorable economic conditions.

That these conditions are being fully recognized is shown by the remarkable record of the past two years, during which period new silk enterprises have been established in upward of 30 Pennsylvania towns and villages, while of a total of 51 new enterprises started in the United States in 1898, Pennsylvania leads with 18, New Jersey coming next with 16, and New York third, with a gain of 8.

Included in the total number (upward of fifty) towns in the State boasting of silk establishments of more or less importance, are Allentown, Alburtis, Altoona, Avoca, Bethlehem, Bath, Bloomsburg, Carlisle, Catasauqua, Columbia, Carbondale, Darby, Danville, Easton, Emaus, Ephrata, Eden, East Greenville, Fleetwood, Freeland, Harrisburg, Hawley, Honesdale, Hanover, Hallstead, Lancaster, Lehighton, Marietta, Mauch Chunk, New Holland, Newberry, Philadelphia, Plymouth, Pottstown, Pottsville, Reading, Rockledge, Scranton, Sunbury, Stroudsburg, Taylor, Titusville, Williamsport, Weatherly, Wilkes-Barre.

Of the total number of 2,340 looms installed in 1898 to equip the 51 new mills, Pennsylvania comes to the front with 1,255, more than half the total number; New York stands next with 510; New Jersey reports 415; Connecticut, 157.

The number of spindles placed in the new throwing mills exceeds 53,000, and Pennsylvania, which is especially strong in this branch, again leads with 37,000, the remainder being divided up between New York (1,800), New Jersey (7,300), Rhode Island and Connecticut.

According to the recent report of Secretary Franklin Allen, of the Silk Association of America, there were in this country, at the beginning of 1899, a total of 27,000 power looms for broad silk weaving and 6,000 power looms for ribbon weaving. In 1890, according to the census returns, there were 14,866 and 4,389, respectively.

A brief review of the various duties on silk, raw and manufactured, from 1790 to the present date will not be devoid of interest in view of the vital importance of protection to this beyond almost any other industry. By the tariff act of 1790, a duty of 7½ per cent. ad valorem was imposed on importations of manufactured silks; by the tariff of 1792, the duty was increased to 10 per cent.; in 1797 it was increased to 12½ per cent.; in 1804, to 15 per cent.; in 1812, to 30 per cent. This was at the time of the war with Great Britain. In 1824 the duty was reduced to 20 per cent. A duty of 15 per cent. was imposed on raw silk in 1823, which, until then had been free.

The sectional excitement of the south against the north resulted, in 1832, in a reduction of the duty on silk manufactures, from this side the Cape of Good Hope to 5 per cent.; from beyond the Cape, 10 per cent. By the same act a duty of 40 per cent. was levied on sewing and 12½ per cent. on raw silk. The duty on all silks, except sewings, manufactured this side the Cape was abolished by Mr. Clay's Compromise Act of 1833, raw silk remaining dutiable at 12½ per cent. There were further provisions of this act looking to a gradual reduction of all duties on foreign imports, which reduced, in time, the duties on sewings to 26 per cent.

By the act of September 11, 1841, the duty on manufactured silk was placed at 20 per cent. In 1842 the duty on silk manufactures was increased to 30 per cent. Raw silk was placed at 50 cents per pound. In 1846, raw silk again was made subject to a duty of 15 per cent., and in 1861, under the "Morill tariff," was made free.* In the year 1857 the duty on manufactured silk was fixed at 24 per cent.; in March, 1861, it was advanced to 30 per cent., in August, of the same year to 40 per cent., and in June, 1861, to 60 per cent. By act of February, 1875, all silk goods containing over 75 per cent. in value of silk were made subject to a duty of 60 per cent.

In 1883, the duty on silk manufactures of a general character was reduced to 50 per cent. This was the year of the Tariff Commission, before which body appeared a delegation of leading silk manufacturers representing that they would be content with a revision downward of 10 per cent. if the duties were made specific, so far as possible. This was because of the serious undervaluation of imports under the ad valorem system, which made it impossible to know, even approximately, what measure of protection was being given. The manufacturers were taken at their word as to the reduction, but ad valorem duties were adhered to in the act.

Under the "McKinley tariff" of 1890, the duty on manufactures of silk was maintained at 50 per cent. In 1893, under the "Wilson tariff," it was reduced to 45 per cent. The Dingley tariff of 1897 increased the duty to 50 per cent., at which it still remains.

In this act, now in force, are included certain specific features ("pound duties") intended to protect against flooding the American market with cheap, light-weight fabrics from Switzerland, Germany, France and the Orient, and this it has accomplished fairly well; a number of foreign manufacturers of this class of goods, having found

*Brockett places the date of the act making raw silk free as 1857, but this is very evidently a mistake. He also makes the act of 1841, fixing the duty on manufactured silk at 20 per cent., to include raw also, and at the same rate of duty. This, also, is obviously an error; the duty on raw remained unchanged, at 12½ per cent., from 1832 to 1842, when it was made 50 cents per pound of 16 ounces, including all silks in the gum, in hanks, reeled or otherwise.

it unprofitable to continue to make them abroad, have removed their plants wholly or in part to this country, thus giving more employment to American labor. Several such plants have been established in Pennsylvania towns since the "Dingley tariff" became operative.

Two staunch and able friends of the silk industry in the Congress of the United States passed away during 1898. Hon. Justin S. Morrill, Senator from Vermont, and Hon. Nelson Dingley, Jr., of Maine, chairman of the Ways and Means Committee of Congress, who framed the tariff act of July, 1897, which bears his name. The "Morrill Tariff Acts" of the period of the Civil War, first gave impetus to silk weaving in America and it was largely through the beneficial results of their provisions that the industry of the country has achieved its present proud position and been crowned with great success as an industrial and commercial fact.

As a mark of esteem of its officers and members, and in appreciation of his great public services, the Silk Association of America sent a suitable wreath for the funeral of Mr. Morrill, at the Senate Chamber, in Washington, on December 31st, last.

COMPARATIVE STATISTICS OF MANUFACTURES. 1892 SERIES.

DAYS IN OPERATION.

COMPARISON OF AVERAGE NUMBER OF DAYS IN OPERATION BY SAME ESTABLISHMENTS FOR EACH OF THE YEARS 1892, 1893, 1894, 1895, 1896, 1897 and 1898.

NOTE.—(In this table the average number of days of employment by the same establishments for each of the years 1892, 1893, 1894, 1895, 1896, 1897 and 1898, is presented, with the relative increase or decrease, together with the increase or decrease 1898 over 1892. Forty-seven industries, representing 358 establishments, are considered.)

BASIC MATERIAL—Continued.

COMPARISON OF AGGREGATE COST OF BASIC MATERIAL—SAME ESTABLISHMENTS FOR THE YEARS 1896, 1897 AND 1898.

Character of Industry and Years.	Number of establishments considered.	Basic material.	Increase (+) or decrease (—) as compared with the preceding year.	Increase (+) or decrease (—) 1898 as compared with 1896.
IRON SPECIALTIES.				
1896,	2	$47,113	.....	.....
1897,	2	77,228	+$30,115	.....
1898,	2	45,879	—31,349	—$1,234
MALLEABLE IRON.				
1896,	4	590,308	.....	.....
1897,	4	455,890	—134,418	.....
1898,	4	698,054	+242,164	+107,746
BOLTS, NUTS, ETC.				
1896,	8	600,739	.....	.....
1897,	8	591,791	—8,948	.....
1898,	8	713,906	+122,115	+113,167
SPIKES AND RIVETS.				
1896,	2	109,498	.....	.....
1897,	2	99,564	—9,934	.....
1898,	2	109,443	+9,879	—55
WIRE NAILS.				
1896,	3	417,134	.....	.....
1897,	3	792,350	+375,216	.....
1898,	3	475,780	—316,570	+58,646
TACKS AND SMALL NAILS.				
1896,	4	48,253	.....	.....
1897,	4	40,862	—7,391	.....
1898,	4	35,049	—5,813	—13,204

BASIC MATERIAL—Continued.

COMPARISON OF AGGREGATE COST OF BASIC MATERIAL—SAME ESTABLISHMENTS FOR THE YEARS 1896, 1897 AND 1898.

Character of Industry and Years.	Number of establishments considered.	Basic material.	Increase (+) or decrease (—) as compared with the preceding year.	Increase (+) or decrease (—) 1898 as compared with 1896.
WIRE.				
1896,	6	$147,605	.....	.....
1897,	6	151,647	+$4,042	.....
1898,	6	192,883	+41,236	+$45,278
WIRE ROPE.				
1896,	2	292,275	.....	.....
1897,	2	230,111	—62,164	.....
1898,	2	248,135	+18,024	—44,140
WIRE GOODS.

RESUME.

THE SAME ESTABLISHMENTS FOR THE YEARS 1896, 1897 AND 1898.

Years.	Number of establishments considered.	Capital invested in plants and fixed working capital.	Value of basic material.	Average number of days in operation.	Number of persons employed.
1896, ...	901	$211,053,779	$99,456,717	268	133,660
1897, ...	901	214,614,083	108,885,762	276	150,078
1898, ...	901	219,027,763	122,120,995	286	165,333

(Note.—Cost basic material, plumbers' supplies, three establishments not included.)

RESUME.

THE SAME ESTABLISHMENTS FOR THE YEARS 1896, 1897 AND 1898.

Aggregate amount of wages paid.	Market value of production.	Value of production during the year to each employe.	Average yearly earnings.	Average daily wage.	Relative per cent. basic material to value of production.	Relative per cent. wages to value of production.
$54,028,185	$202,410,382	$1,514 37	$404 22	$1 51	49.1	26.7
56,497,999	220,092,603	1,466 52	376 46	1 36	49.5	25.7

NOTE.—In basic material eliminating the three plumbing establishments.

SILK MANUFACTURE FOR 1898.

Total number of establishments engaged in silk manufacture during 1898,	88
Total number of spindles, 699,308;	
Winding and doubling,	179,723
Spinning and twisting,	482,699
Braiding,	36,886
Total number of hand looms, 177;	
Plain broad goods,	36
Jacquard,	54
Narrow goods,	87
Total number of power looms, 9,238;	
Plain broad goods,	5,234
Jacquard,	1,748
Ribbons,	1,447
Other narrow goods,	809
Total number of machines, 3,401;	
Knitting and lace,	268
Sewing,	201
Braiding,	2,932
Total number of employes, 20,365;	
Males over 16 years of age,	5,441

Females over 16 years of age,	10,998
Children between the ages of 13 and 16,	3,926

Aggregate wages paid, $4,866,851;

Males,	$2,022,586
Females,	2,371,254
Children,	473,011

Average number of weeks in operation,	51

Total value of production, $32,250,599, classified as follows:

Tram and organzine,	$11,223,898
Yarns,	2,977,140
Spool silk, floss, etc.,	725,000
Ribbons,	4,327,274
Dress silks, satins, plushes and other broad goods,	10,889,464
Miscellaneous products,	2,107,823

SILK MANUFACTURE—Continued.

PRODUCTION OF BROAD GOODS AND RIBBONS.

Broad Goods,	18,870,096 yds.
Ribbons,	69,532,622 yds.

AVERAGE YEARLY EARNINGS.

Males,	371 73
Females,	215 61
Children,	120 48

VE E WEEKLY EARNINGS.

Males,	7 29
Females,	4 23
Children,	2 36
Value of production per employe,	1,587 75
Relative per cent. of wages to value of production,	15.0

RESUME OF SILK MANUFACTURE FOR THE YEAR 1898.

Total number of establishments in operation,	88
Total number of spindles,	699,308
Total number of hand looms,	177
Total number of power looms,	9,238
Total number of machines,	3,401
Weeks in operation,	51
Number of persons employed,	20,365
Aggregate wages paid,	$4,866,851
Value of production,	$32,250,599

SILK MANUFACTURE—Continued.

ANALYSIS.

The first tables presented are those of the 1892 comparative series, pages 71 to 201. Forty-seven industries are set forth, representing 358 establishments, which are carried throughout the entire series and comparison made from year to year of the days in operation, persons employed, aggregate of wages paid, average yearly earnings, value of the production and the average value of the production per employe. As these tables are of value, more especially as indicating business conditions, it would be well to follow them closely, and not only this series, but the 1896 comparative series which immediately follows.

It will be seen, in the 1892 series, that 138,762 wage earners, skilled and unskilled, were employed in the 358 establishments during 1898. In 1892, the year of our greatest prosperity, the number employed was 137,612, or 1,150 less than during 1898. In 1894, the year of our greatest depression, there were employed only 110,071, an increase in 1898 over 1894 of 28,691, or 26 per cent.

The aggregate of wages paid out during 1898 was $62,960,638, being $4,545,176 less than was paid out in 1892, or 6.73 per cent. of a decrease, but an increase over that paid out in 1897 of $10,554,322, or 20.14 per cent., and an increase over 1894 of $17,501,625, or over 38 per cent.

The increase in yearly earnings in 1898 over 1897 was $24.15, or 5.62 per cent., and over 1894, $40.73, or nearly 10 per cent.

The value of the product of these 358 establishments for 1898 was $267,048,287, as against $270,359,609 in 1892, a decrease of $3,311,332, or over 1 per cent. The increase in 1898 over 1897 was $43,158,838, or over 19 per cent., and the increase over 1894, the year of the greatest depression, was $80,662,040, or over 43 per cent.

The following table shows the only industries in this series having a decrease in the number of persons employed:

DECREASE IN THE NUMBER OF PERSONS EMPLOYED.

Industries.	Number.
Car couplers,	30
Carpets,	373
Worsted yarns,	15
Miscellaneous yarns,	29
Worsted goods,	27

Knit goods,	30
Hosiery and knit goods,	67
	571

The remaining 40 industries show an increase of 17,338 persons employed, or over 14 per cent.

The following table shows the only industries with a decrease in the aggregate of wages paid:

DECREASE IN THE AMOUNT OF WAGES PAID.

Industries.	Wages.
Nails and spikes,	$37,782
Car couplers,	19,898
Carpets,	158,403
Worsted yarns,	26,011
Miscellaneous yarns,	23,616
Worsted goods,	12,367
Knit goods,	431
Chenille goods,	14,849
Hosiery and knit goods,	14,788
Ribbons,	3,965
	$312,110

The remaining 37 industries show an increase of $10,866,432 in wages paid, or 20.7 per cent.

The following table shows the decreases in the value of the production:

DECREASE IN THE VALUE OF PRODUCTION.

Industries.	Value.
Plate and bar,	$143,768
Nails and spikes,	403,008
Carbons,	5,000
Carpets,	523,715
Cotton yarns,	36,444
Worsted yarns,	208,114
Miscellaneous yarns,	223,436
Knit goods,	32,000
Hosiery and knit goods,	19,483
Ribbons,	5,394
	$1,600,362

The remaining industries in this series show increases in the value of production amounting to $44,759,200, or 19.9 per cent.

1896 COMPARATIVE SERIES.

In this series comparison cannot be made with 1892 and 1894 for the reason that the series was not commenced until 1896. Statistics relating to this series will be found on pages 202 to 419.

This series comprises 101 industries, representing 901 establishments. It will be seen that in capital invested there has been a gradual increase since 1896, and that in 1898 the capital invested was $219,027,763, or an increase over 1897 of 2.06 per cent. and over 1896 of 3.77 per cent.

There has been a still larger increase in the value of the basic material out of which the product was made. By basic material is meant that material out of which the product is produced, and at no time includes fuel or other costs of manufacture. For instance, in the case of pig iron, it means the ore, crap or cinder out of which the pig iron is made. In case of a finished product of iron, it means the cost of the iron at whatever stage it entered the mill for manufacture. If a woolen production, say, yarns, it means the cost of the wool. If a cotton production, the cost of the cotton. If a silk production, the cost of the silk, and so on. If the product be a woven fabric, and the mill should not make its yarns, but buy them, then the cost of the yarns is the cost of the basic material; that is to say, basic material means the material out of which the product is made at whatever stage it enters the mill. It will consequently be seen that the figures herein presented cannot lead up to the cost of manufacture, as there are many important items of expense yet to be considered.

The value of the basic material used by these 901 establishments in 1898 was $122,120,995, or an increase over 1897 of 12.16 per cent., and over 1896 of 22.79 per cent.

The average days of operation in 1898 was 286 as against 276 in 1897 and 268 in 1896.

The total number of working people, skilled and unskilled, employed in 1898 was 165,333, or an increase over 1897 of 15,254, or 10.16 per cent., and over 1896 of 31,673, or 23.69 per cent. The aggregate of wages paid to these working people in 1898 was $65,078,302, an increase over 1897 of 15.19 per cent., and over 1896 of 20.45 per cent. The average yearly earnings were $393.62, or an increase over 1897 of 4.56 per cent., but a decrease from 1896 of 2.62 per cent. The average daily wage in 1898 was $1.38, in 1897, $1.36, and in 1896, $1.51.

The value of the production in 1898 was $254,683,443, or an increase over 1897 of 15.72 per cent., and over 1896 of 25.83 per cent. The value of the production to each employe for 1898 was $1,540.42, an increase over 1897 of 5.04 per cent., and over 1896 of 1.72 per cent.

The following table shows the only industries in this series having a decrease in the number of persons employed:

DECREASE IN THE NUMBER OF PERSONS EMPLOYED.

Industries.	Number.
Iron and steel specialties,	21
Iron specialties,	10
Tacks and small nails,	46
Wrenches, picks, etc.,	21
Saws,	3
Safes and vault doors,	4
Iron beds,	3
Paper manufacture,	38
Cordage, rope, etc.,	23
Building brick,	29
Slate roofing, etc.,	52
School slates,	18
Umbrellas and parasols,	88
Neckwear,	17
Cotton and woolen cloth,	29
Clothing,	272
Woolen and worsted fabrics,	148
Woolen and worsted yarns,	67
Rugs, yarns, etc.,	143
Carpet yarns,	48
Chenille goods,	59
	1,140

The remaining 80 industries show increases of 13,392 in the number employed, or 10.9 per cent.

The following table shows the decreases in the aggregate of wages paid:

DECREASE IN THE AGGREGATE OF WAGES PAID.

Industries.	Wages.
Iron and steel specialties,	$14,245
Iron specialties,	4,000
Wire nails,	62,912
Tacks and small nails,	7,269
Bicycles,	2,744
Pianos and organs,	716
Tinware,	3,788
Paper manufacture,	14,619
Cordage, rope, etc.,	7,030
Building brick,	28,510
Slate roofing,	19,986

School slates,	$2,357
Hats and caps,	2,953
Umbrellas and parasols,	42,684
Neckwear,	2,566
Carpets,	17,932
Clothing,	9,785
Woolen and worsted yarns,	36,597
Carpet yarns,	43,173
Worsted yarns,	22,324
	$346,190

The remaining 81 industries show increases amounting to $8,926,493, or 15.8 per cent.

The following table shows the decreases in the value of the production:

DECREASE IN THE VALUE OF PRODUCTION.

Industries.	Value.
Steel billets, etc.,	$252,328
Iron and steel specialties,	24,404
Iron specialties,	41,060
Wire nails,	437,825
Tacks and small nails,	12,950
Bath boilers, tanks, etc.,	1,597
Car wheels and car axles,	5,190
Safes and vault doors,	4,391
Building iron work,	305
Pianos and organs,	36,003
Paper manufacture,	114,716
Building brick,	88,400
School slates,	20,675
Hats and caps,	44,911
Wool hats,	16,802
Umbrellas and parasols,	99,487
Neckwear,	20,842
Clothing,	72,438
Rugs, yarns, etc.,	96,988
Carpet yarns,	386,195
Worsted yarns,	455,652
Cotton and woolen yarns,	54
	$2,233,213

The remaining 79 industries show increases amounting to $36,824,053, or 16.7 per cent.

The production is given in these tables of only 46 out of the 101 industries, for the reason of incompleteness in returns of production for the remaining 55 industries.

Of 20 miscellaneous iron industries giving production, only 4 show decreases in tonnage. They are iron and steel specialties, iron specialties, wire nails and tacks and small nails, and their decreases are 14,638 tons. The remaining 16 industries show an increase of 213,843 tons, or nearly 18 per cent. over the production of 1897.

Paper manufacture, 10 establishments represented, shows a decrease in product of 9 per cent.; wall paper, 5 establishments represented, shows an increase of 19.2 per cent.; cigars, 50 establishments represented, show an increase of 4.8 per cent.; paving and building brick, 50 establishments represented, show an increase of 23.5 per cent.; roofing slate, 17 establishments represented, shows an increase of 19 per cent.; glazed and chrome kid, 7 establishments represented, show an increase of 16.9 per cent.; men's, women's, misses' and children's shoes, 18 establishments represented, show an increase of 2.1 per cent.; suspenders, 2 establishments represented, show an increase of 8.5 per cent.; hats and caps, 3 establishments represented, show a decrease of 3.2 per cent.; fur and felt hats, 5 establishments represented, show an increase of 9.6 per cent.; wool hats, 8 establishments represented, show an increase of 1.4 per cent.; umbrellas and parasols, 6 establishments represented, show a decrease of 5.1 per cent.; shirts and shirt waists, 11 establishments represented, show an increase of 71.1 per cent.; carpets, 20 establishments represented, show a decrease of 5.2 per cent.; woolen and worsted yarns, and worsted yarns, 22 establishments represented, show a decrease of 26.3 per cent.; carpet yarns, 12 establishments represented, show a decrease of 18.1 per cent.; cotton yarns, and cotton and woolen yarns, 13 establishments represented, show an increase of 6.8 per cent.; hosiery, 34 establishments represented, show a decrease of 3.5 per cent.; silk, broad goods, etc., 3 establishments represented, show an increase of 8.3 per cent.; ribbons, 4 establishments represented, show an increase of 35.4 per cent.

SILK MANUFACTURE.

Statistics relating to the manufacture of silk in Pennsylvania for 1898 will be found on pages 420 to 427. Comparison is made between the Federal Census of 1890 and the Bureau Census of 1895.

The number of spindles in 1898 was 699,308, an increase over 1895 of 141,816, or 25.4 per cent.; the number of hand looms, 177, a decrease from 1895 of 128, or 42 per cent.; the number of power looms, 9,238, an increase over 1895 of 3,546, or 62.2 per cent.; the number of machines, 3,401, an increase over 1895 of 1,121, or 49.2 per cent. The falling off in the number of hand looms is easily accounted for, as the hand loom is fast giving place to the improved power loom.

The number of males employed in 1898 was 5,441, as against 3,853 in 1895, an increase of 1,588, or 41.3 per cent.; the number of females employed was 10,998, as against 6,394, an increase of 4,064, or 58.6 per cent.; the number of children employed was 3,926, as against 3,028, an increase of 898, or 29.6 per cent., making a total of 20,365 employes in 1898, as against 13,815 in 1895, an increase of 6,550, or 47.4 per cent., and an increase over the number in 1890 of 11,035, or 118.3 per cent.

The average yearly earnings of the males in 1898 was $371.73; of the females, $215.61; of the children between thirteen and sixteen years of age, $120.48. The weekly earnings of the males in 1898 was $7.29; of the females, $4.23; of the children, $2.36. Comparison is not made as to classified earnings for the reason that separation of wages was not given in 1895.

The value of the production in 1898 was $32,250,599, as against $24,184,583 in 1895, an increase of $8,066,016, or 33.1 per cent., and an increase over 1890 of $12,893,053, or 66.6 per cent.

PIG IRON.

Pig iron production for 1898, in comparison with the years 1897 and 1896, will be found on pages 428 to 431.

It will be seen that in 1898 Pennsylvania produced 5,367,979 gross tons of pig iron, not including some 40,000 tons of spiegeleisen and ferro-manganese, sometimes included in pig iron production, as against 4,617,634 tons produced in 1897, an increase of 750,345 tons, or 16.2 per cent., and an increase over 1896 of 1,341,629 tons, or 33.3 per cent.

The value of the pig iron production for 1898 was $53,331,228, as against $48,884,854 in 1897, an increase of $4,446,374, or 9.1 per cent., and 18 per cent. of an increase over 1896. The average value per ton in 1898 was $9.94, as against $10.58 in 1897, a decrease of 64 cents per ton, or 6 per cent., and a decrease from 1896 of $1.27 per ton, or 11.3 per cent. The aggregate cost per ton of the basic material in 1898, that is, the ore, scrap or cinder out of which the pig iron was made, was $5.48, as against $6.48 in 1897, a decrease of $1.00 per ton, or 15.4 per cent., and a decrease from the cost in 1896 of $1.04 per ton, or 16 per cent.

The number of working people employed in 1898 was 11,911, as against 11,272 in 1897, an increase of 639 persons, or 5.6 per cent., and an increase over 1896 of 2.8 per cent.

The aggregate amount of wages paid out in 1898 was $5,268,503, as against $4,676,970, in 1897, an increase of $591,533, or 12.6 per cent., and an increase over 1896 of 14.8 per cent. The average yearly earnings in 1898 were $442.32, an increase over 1897 of $27.40, or 6.6 per cent., and an increase over 1896 of $46.02, or 11.6 per cent. The average daily wage in 1898 was $1.32, in 1897, $1.36 and in 1896, $1.37.

The average cost of labor per ton in 1898 was 98 cents; in 1897, $1.01, and in 1896, $1.14.

STEEL PRODUCTION.

Statistics relating to the steel production in Pennsylvania for 1898 will be found on pages 432 to 434.

The production of bessemer steel in 1898 was 3,357,684 gross tons, as against 2,848,204 tons in 1897, an increase of 509,480 tons, or 17.9 per cent., and an increase over the production of 1896 of 1,064,870 tons, or 46.44 per cent. The production of open hearth in 1898 was 1,848,732 tons, as against 1,421,373 tons in 1897, an increase of 427,359 tons, or 30.1 per cent., and an increase over the production of 1896 of 839,124 tons, or 83.11 per cent. The production of crucible steel in 1898 was 69,568 tons, as against 49,245 tons in 1897, an increase of 20,323 tons, or 41.2 per cent., and an increase over the production of 1896 of 26,461 tons, or 61.38 per cent., making the total production of steel for 1898 5,275,984 gross tons, as against 4,318,622 tons in 1897, an increase of 957,362 tons, or 22.2 per cent., and an increase over the production of 1896 of 1,930,455 tons, or 57.7 per cent.

IRON AND STEEL ROLLED INTO FINISHED FORM.

Statistics relating to the production of iron and steel rolled into finished form will be found on pages 435 to 439.

Neither billets nor puddle bar are included in the production of iron and steel rolled into finished form, as the Bureau does not treat them as a finished form of rolled iron and steel.

The capital invested in 1898 was $130,795,783, as against $126,170,391 in 1897, an increase of $4,625,392, or 3.7 per cent., and an increase over 1896 of $10,174,871, or 8.4 per cent.

The production in 1898 was 5,537,249 net tons, as against 4,714,333 tons in 1897, an increase of 822,916 tons, or 17.4 per cent., and an increase over the production of 1896 of 1,780,179 tons, or 47.3 per cent.

The value of the production in 1898 was $136,820,442, as against $123,900,771 in 1897, an increase of $12,919,671, or 10.4 per cent., and an increase over the value of 1896 of $17,790,680, or 14.9 per cent. The average value per net ton in 1898 was $24.71, as against $26.28 in 1897, a decrease of $1.57 per ton, or 5.09 per cent., and a decrease from the value in 1896 of $6.97 per ton, or 22 per cent.

The average cost of the basic material per ton of finished product, that is, the iron and steel only out of which the rolled product was made, in 1898 was $14.43, as against $16.53 in 1897, a decrease of $2.10, or 12.7 per cent., and a decrease from 1896 of $3.89 per ton, or 21.2 per cent.

The number of working people employed, skilled and unskilled, in 1898, was 56,230, an increase over 1897 of 3.432, and an increase over 1896 of 2,657.

The average yearly earnings of the working people in 1898 were $495.81, as against $461.19 in 1897, an increase of $34.62, or 7.5 per cent., and an increase over 1896 of $50.92, or 11.4 per cent. The average daily wage in 1898 was $1.78, as against $1.71 in 1897 and $1.77 in 1896.

TIN PLATE.

The statistics relating to tin plate production in Pennsylvania will be found on pages 440 to 445. The census of 1898 is compared with that of 1897 and 1896.

The number of plants in operation making black plate in 1898 was 18, as against 15 in operation in 1897.

The quantity of black plate produced in 1898 was 344,064,000 pounds, as against 254,157,601 pounds produced by the 15 plants in operation in 1897, an increase of 89,906,399 pounds, or 35.4 per cent., and an increase over the production of the 13 plants in operation in 1896 of 185,757,510 pounds, or 117.3 per cent.

Of the 18 black plate works in operation in 1898, only 15 turned out a tinned production. Their output was 222,528,000 pounds, as against 179,705,766 pounds produced in 1897, an increase of 42,822,234 pounds, or 23.8 per cent., and an increase of tinned production over 1896 of 124,713,238 pounds, or 127.5 per cent.

The value per ton of 2,000 pounds of the black plate produced in 1898 but not tinned was $43.83, as against $44.51 in 1897, a decrease of 68 cents, or 1.5 per cent., and a decrease from the value in 1896 of $5.10 per ton, or 10.4 per cent.

The average value per 100 pounds of tinned and terned plate produced by the black plate works in 1898 was $3.01, as against $2.88 in 1897, an increase of 13 cents, or 4.5 per cent., but a decrease from the value in 1896 of 22 cents per ton, or 6.8 per cent.

The number of working people employed, skilled and unskilled, in 1898 was 5,036, as against 3,920 in 1897, an increase of 1,116, or 28.5 per cent., and an increase over 1896 of 1,842, or 57.7 per cent.

The average yearly earnings in 1898 were $584.58, as against $568.17 in 1897, an increase of $16.41, or 2.9 per cent., and an increase over 1896 of $128.03, or 25.8 per cent. The average daily wage for skilled and unskilled labor in 1898 was $2.10, as against $2.02 in 1897, an increase of 8 cents, or 4 per cent., and as against $1.80 in 1896, an increase of 30 cents per day, or 16.7 per cent.

Pennsylvania has two tin plate works that produced no black plate in 1898, P. H. Laufman, Limited, and the large new tin plate works of the Shenango Valley Steel Company, which was only ready for operation at the beginning of the year.

The total number of hot mills in the State was 138; total number of tinning sets, 197; daily capacity, 1.069 net tons.

DIPPING WORKS.

Pennsylvania had seven tin plate dipping works in operation in 1898. Number of tinning sets, 55; daily capacity, 109 net tons. By dipping works is meant a tin plate concern that turns out a tin plate production from purchased black plate. They are tin plate makers, not black plate makers. These seven plants produced 40,406,000 pounds of tin and terne plate, the average value of which was $4.32 per hundred. This increased value over that of the black plate works is due largely to the fact that much roofing tin is included, which is more expensive than the ordinary plate.

The average yearly earnings of the employes, many of whom were girls, were $302.22, and the average daily wage was $1.17.

The combined output of tin and terne plate of the black plate works and the dipping works for 1898 was 262,934,000 pounds, with a total value of $8,445,097, and an average value per 100 pounds of $3.21.

A better idea of the growth of the tin plate industry in Pennsylvania can be had by making comparisons with 1894. In that year, the total output of black plate was 104,757,360 pounds, which, as against 344,064,000 pounds, made in 1898, shows an increase in the four years of 239,306,640 pounds, or 228 per cent.

LIMESTONE PRODUCTION.

Statistics relating to the production of limestone in the State for iron manufacturing purposes will be found on pages 448 and 449.

It will be seen that the production in 1898 was 4,200,523 gross tons, with a value of $1,305,566.

The number to whom employment was given in quarrying this output, including boys, was 2,481, with average yearly earnings of $308.33, or $1.15 per day, with 269 days of employment. Blair county produced 37.75 per cent. of the entire output of the State; Lawrence county followed with 23.32 per cent. No other county reached 10 per cent.

In connection with the relative per cent. by counties, it will be seen that Allegheny county retains her strong lead in the production of pig iron, steel and iron and steel rolled into finished form, her relative per cent. in 1898, of the production of pig iron being 52.29, of steel 64.59, of iron and steel rolled into finished form 57.52. Eighteen county produced pig iron, Centre county being at the foot of the list with .02 per cent. Eighteen counties produced steel, Crawford being at the foot of the list with a relative percentage of .0015. Thirty-two counties produced iron and steel rolled into finished form, Crawford being at the foot of the list with a relative percentage of .001. Ten counties produced black plate, Lawrence leading with a relative percentage of 38.54, and Cambria, being at the foot with a relative percentage of 1.09. Nine of these ten counties turned out a

tin plate production, Lawrence leading with a relative percentage of 31.10, and Cambria closing the list with a relative percentage of .08. The dipping works are confined to four counties, Philadelphia, Allegheny, Montgomery and Berks, Philadelphia leading with a relative percentage of 71.47, and Berks being at the foot, with a relative percentage of 1.86. Eleven counties, combining the black plate works and dipping works, were producers of tinned plate, Lawrence county leading with a relative percentage of 26.32, and Cambria closing the list with a relative percentage of .07.

The following averages of daily wage are taken from the 1896 series, from the census of silk, pig iron, iron and steel rolled into finished form, tin plate and limestone. The aggregate of persons employed from which these averages are made is 250,322, which includes skilled and unskilled labor, males, females and children, the corresponding aggregate of wages amounted to $104,609,942, or a per capita for all employed of $417.90. They represent a value for the various products produced by these working people amounting to the enormous sum of $482,089,010. It will be noticed that from hats and caps down the average daily wage drops rapidly from $1.10 to 70 cents. While in many industries preceding hats and caps, there is much female help employed, yet the explanation of the very low average that follows is readily understood when it is seen that the help in these establishments is not only largely female, but that many boys and children are employed:

Steam pumps,	$2 44

Brass, copper and bronze goods,	1 50
Iron chains,	1 50
Pottery,	1 50
Iron fences and railings,	1 49
Fire brick,	1 49
Men's, women's, misses' and children's shoes (males),	1 47
Steel castings,	1 46
Tacks and small nails,	1 45
Car wheels and car axles,	1 43
Slate roofing, etc., (squares),	1 43
Wrought iron pipe and tubes,	1 42
Bath boilers, tanks, etc.,	1 41
Paper manufacture,	1 41
Paving brick,	1 33
Pig iron,	1 32
Glazed and chrome kid,	1 32
Cotton and woolen cloth,	1 32
Upholstery goods,	1 32
Slate roofing, etc. (tonnage),	1 31
Wall paper,	1 30
Cast iron pipe,	1 29
Metal and metallic goods,	1 29

Carpet yarns,	$1 27
Bolts and nuts,	1 26
Carpets,	1 24
Tinware,	1 24
Spikes and rivets,	1 23
Freight and street cars,	1 23
Silk (males),	1 21
Neckwear,	1 20
Woolen and worsted cassimere,	1 20
Rugs, yarns, etc.,	1 20
Tin plate (dipping works),	1 17
Woolen and worsted yarns,	1 17
Files, etc.,	1 15
Limestone,	1 15
Hats and caps,	1 10
Cotton goods,	1 10
Suspenders,	1 09
Cotton and woolen yarns,	1 08
Wool hats,	1 07
Woolen and worsted yarns,	1 05
Cordage, rope and twine,	1 03
Cotton yarns,	1 02
Iron and steel specialties,	1 00
Cigars,	99
Knit goods, underwear, etc.,	96
Worsted yarns,	95
Woolen blankets, flannel, etc.,	94
Chenille goods,	92
Dress trimmings, braids, etc.,	90
Shirts and shirt waists,	90
Lace goods,	90
Umbrellas and parasols,	88
Hosiery,	88
Men's, women's, misses' and children's shoes (females),	87
Wire goods,	86
School slates,	85
Iron beds,	76
Paper boxes, envelopes, etc.,	76
Silk (females),	70

INDEX.

	Page.
COMMUNICATION,	1
LETTER OF TRANSMITTAL,	3
INTRODUCTION,	5-6
ARE ECONOMICS OF VALUE IN THE PHILIPPINES,	7-18
SILK INDUSTRY,	19-69
Character of fibre,	19
Bomby cidae family,	20
The Moth,	21
The Worm,	21
The Cocoon,	21
Weaving from the Cocoon,	22
Modus operandi.	23
Cheap labor in the Orient,	23
About spun silk,	23
Some marvelous machinery,	24
Spider silk,	24
An ingenious device,	25
Some other substitutes,	25
The fremery—Urben substitute,	26
SILK INDUSTRY—From fibre to fabric,	27-35
Initial processes in silk fabrication,	27
Highly improved sewing machinery,	28
Dyeing the silk,	29
Advance in color work,	29
Weighting,	29
Making the warp,	31
The primitve loom,	31
The Power loom,	31
The Jacquard loom,	33
The Jacquard before Napoleon,	33
The Dobby,	33
Revolution in the ribbon branch,	33
Warp printing,	34
Piece dyeing and printing,	34
Sewings and twists silk thread, etc.,	35
SILK—Outline history,	35-50
A textile of royal birth,	35
The secret jealously guarded,	36
Silk tissue in profligate Rome,	36
Silk worm in Japan,	36
Secret escape from China,	36
Westward, the march of his wormship,	37
Under royal patronage,	37
The silk worm in England,	37
John Lombe died by poison,	39
Ruined by free trade,	39
Silk worm in America,	40

SILK—Continued.
Cortes as promoter of sik industry, ... 40
Taffetas produced, ... 40
Another royal patron, ... 40
Silk appears in Virginia, ... 41
Earliest quotation for raw-silk, ... 42
Silk as an evangelist, ... 42
Silk industry in the Carolinas, ... 43
Silk culture by negroes, ... 43
Carolina silk for royal wear, ... 44
Abbe Raynal's ingenious theory, ... 44
Silk culture extended to Louisiana and Georgia, ... 44
Queen Caroline in Georgia silk, ... 45
Erroneous report of production, ... 46
Liberal bounties offered, ... 47
Royal favor to silk culturists, ... 47
After the Revolution, ... 47
Silk culture in Connecticut, ... 47
Silk in Massachusetts, ... 48
Morus multicaulis madness, ... 48
Father of the American silk industry, ... 48
A small beginning in Paterson, ... 48
New York market bare of silk, ... 49
An expanding industry, ... 49
Present status, ... 49
Comparative statistics, ... 50
IMPORTS OF RAW SILK, ... 50-52
Domestic production versus consumption, ... 51
Beginning of silk manufacture, ... 51
SILK INDUSTRY IN PENNSYLVANIA, ... 52-68
Silk culture encouraged, ... 53
Liberal bounties paid, ... 53
Dr. Franklin a friend of silk culture, ... 54
A public filature in Philadelphia, ... 54
Silk manufacture in Pennsylvania household, ... 55
Washington presented with a piece of silk goods, ... 55
Manufacturer's discouraged, ... 56
Crude and primitive processes, ... 56
Sewing silk as a circulating medium, ... 56
Badly reeled fibre, ... 57
Congress asked to encourage silk culture, ... 58
Flags of American silk, ... 59
The beginning of a craze, ... 59
An auction sale of multicaulis, ... 61
Subsequent attempt at silk culture, ... 62
The Women's Silk Culture Association, ... 62
Legislative aid denied, ... 63
Silk manufactured in five states, ... 65-66
What the twelfth census will show, ... 66
Some Pennsylvania "silk towns," 67
A review of silk duties, ... 67
Raw silk made free of duty, ... 68
A bid for specific duties, ... 68
STATISTICS OF MANUFACTURES 1892 COMPARATIVE SERIES OF 1892-1898, ... 71-202
Comparison of days in operation, ... 71-86
Comparison of persons employed, ... 87-102
Comparison of aggregate wages paid, ... 103-118
Comparison of average yearly earnings, ... 119-134

Page.
STATISTICS OF MANUFACTURES—Continued.
Comparison of average daily wage, ... 135-150
Comparison of value of product, ... 151-166
Comparison of value of annual product per employe, ... 167-183
Recapitulation of comparative table by years, ... 184-199
Resume, ... 200
Comparison of totals, ... 201
STATISTICS OF MANUFACTURES, 1896, COMPARATIVE SERIES OF 1896-1898, ... 202-419
Comparison of capital invested, ... 202-218
Comparison of value of basic material, ... 219-235
Comparison of days in operation, ... 236-252
Comparison of persons employed, ... 253-269
Comparison of aggregate wages paid, ... 270-286
Comparison of value of product, ... 287-303
Comparison of value of average annual product per employe, ... 304-320
Comparison of average yearly earnings, ... 321-338
Comparison of average daily wage, ... 339-355
Comparison of relative per cent. basic material to value of production, ... 356-372
Comparison of relative per cent. wages to value of production, ... 373-389
Comparison of production in tons or quantity, ... 390-397
Recapitulation of comparative table by years, ... 398-415
Resume, ... 416-417
Comparison of totals, ... 418-419
SILK MANUFACTURE, ... 420-427
Silk manufactured for 1898, ... 420-421
Comparison, silk manufacture, 1890-1898, ... 422-424
Resume of machinery, spindles, etc., 1895-1898, ... 425
Resume of silk manufacture, ... 426-427
PIG IRON PRODUCTION, 1898, ... 428
Comparison of pig iron production for the years 1896-1897 and 1898, .. 429-430
Production of pig iron by counties, ... 431
PRODUCTION OF STEEL, 1898, ... 432
Production of steel, 1898, as compared with 1896 and 1897, ... 433
Production of steel by counties, ... 434
PRODUCTION OF IRON AND STEEL ROLLED INTO FINISHED FORM, 1898, ... 435-439
Comparison of iron and steel rolled into finished form for the years 1896, 1897 and 1898, ... 436-437
Production by counties with relative per cent., ... 438-439
TIN PLATE, ... 440-447
Production of black plate works, 1898, ... 440
Black plate works, 1898, as compared with 1896 and 1897, ... 441-442
Black plate production by counties, ... 443
Production of tin and terne plate by counties and relative per cent., 444
Total tin plate production by counties, ... 445
Production of tin plate dipping works, 1898, ... 446
Combined production of black plate and dipping works, ... 446
Combined production of tin and terne plate by the black plate and dipping works, 1898, as compared with 1896 and 1897, ... 447
Tin and terne plate by counties (dipping works), ... 448
LIMESTONE QUARRIED FOR IRON MANUFACTURING PURPOSES, ... 448
Limestone production by counties, ... 449
ANALYSIS, ... 450
Comparative series, 1892, ... 450
Industries showing decrease in the number of persons employed, .. 450
Industries showing decrease in the amount of wages paid, ... 451

ANALYSIS—Continued.
